The PRESIDENT, in moving the adoption of the report of the council, congratulated the members of the union on the satisfactory condition of their affairs. Their financial position was absolutely sound, their work increased as their members increased, and so did their expenses, but correspondingly their income increased. At the end of the year they had in hand £1100 and that was a sufficient proof of the vitality of the union. They had had a quiet year but the work had been very important. The union had lost the services of Dr. W. S. A. Griffith as president through his resignation. The choice of president had fallen on himself which he accepted as a compliment to the provinces. The system of auditing their accounts had been altered and the auditor was paid a somewhat larger sum so as to ensure more perfect security against irregularities. The case of Martin v. Allen referred to in the report of the council was of great importance. It was a case in which a matron at a hospital in Belper had brought an action for libel against one of their members. After three days' trial the jury failed to agree as to a verdict. The case was re-tried and though the union gained a moral victory the case was lost by them. That case, however, was the only one lost during the year. In regard to the Consultative Institute of Birmingham and Dr. Irvine he did not think it necessary to go into details. That matter was absolutely closed. The Consultative Institute of Birmingham had come to an end owing to the action taken by the council of the union in charging Dr. Irvine before the General Medical Council. In consequence of what they had done it had been found impossible to get any medical man to take the appointment offered by the institute. Referring to the case of Dr. R. Rendall he reminded them that the General Medical Council had passed a resolution strongly disapproving of practitioners associating themselves with medical aid societies that touted for patients. That resolution did not carry anything penal with it but the union considered that it would be right to take before the General Medical Council a definite case and the results of their action in regard to Dr. Rendall had been in every way satisfactory. As a matter of fact, since the decision of the General Medical Council medical practitioners associated with these medical aid societies had resigned wholesale and so far as could be gathered from the reports which reached the union the societies involved would find it extremely difficult, if not impossible, to obtain men to fill the vacancies. He thought that case ought to be well known to all members of the medical profession, and he thought that medical men who remained associated with medical aid societies who touted for patients should sever themselves from those institutions. If they did not do so the union would consider the advisability of taking further cases before the General Medical Council. In regard to the expenses incurred for legal work 12 cases involved a total expenditure of £989 but in the remainder the expenditure was not heavy. He emphasised the fact that the Medical Defence Union was quite prepared to fight for, and to defend, their members and never compromised. They were able to do this regardless of what was paid for the defence of any particular member. He thought that that ought to be known because there were many members of the profession who were forgetful of the fact that at any time they might be involved in an action which they would have to defend for themselves. Their solicitor, Mr. W. E. Hempson, said that his experience was that the medical man of all professional men was the one almost invariably selected for speculative actions. Dr. W. T. Law, who successfully defended an action brought against him that was denounced by the judge as a ridiculous one, was in the end obliged to pay £700 for costs. Dr. Law was not a member of that union and appeals for help had appeared in the medical journals. He himself thought that such appeals were not right and it was his opinion that the general body of the profession were of the same opinion.

The motion for the adoption of the report was seconded by Mr. A. C. ROPER and carried unanimously.

Mr. T. GUNTON ALDERTON moved, and Dr. M. BEVERLEY seconded, the adoption of the accounts which was carried unanimously.

Dr. J. S. FENNIS proposed that £100 be paid to provincial members of the council *pro rata* for railway fares when attending council meetings.—This was formally seconded and carried unanimously.

Dr. W. A. Elliston, J.P., Mr. J. Roche Lynch, and Mr. V. A. Jaynes were re-elected members of the council, and upon the suggestion of Mr. P. ROSE, supported by Mr. R. F. TOMLIN, the PRESIDENT intimated that Mr. J. T. Macnamara would be elected a vice-president with a seat on the council.

Dr. H. W. LANGLEY BROWNE proposed the re-election of the auditor, Mr. L. Hardy.—This was seconded by Dr. W. RIGDEN and carried unanimously.

Mr. STAMFORD FELCE moved a vote of thanks to the solicitor to the union, Mr. W. E. Hempson, and to the general secretary, Dr. A. G. Bateman.—This was seconded by Dr. M. BEVERLEY and after being carried unanimously was replied to by the officials named.

A hearty vote of thanks to the President for taking the chair was accorded on the motion of Dr. W. S. A. GRIFFITH.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

THIS annual exhibition, which was opened at Queen's Hall, Langham-place, on May 20th, continues to play a useful rôle inasmuch as it affords general practitioners, surgeons, hospital nurses, and others in London an opportunity of making acquaintance with the newest special foods and drugs and surgical and sanitary appliances. The organising committee may be congratulated on now having established an annual event which has secured for its *clientèle* a very fair proportion of the medical profession. The exhibition is distinctly instructive, although it is true that many well-established preparations, drugs, and appliances are on view again and again, yet there will invariably be found some novelties marking the progress of medical science in its various collateral branches. At any rate, the increasing number of physicians, surgeons, and the members of hospital staffs who attend must be a very encouraging fact to those concerned in organising the exhibition.

A feature of the exhibition this year was the number of electrical appliances shown. Thus, the exhibit of the General Electric Company, 67, 69, 71, 88, and 92, Queen Victoria-street, E.C., attracted a good deal of interest chiefly perhaps on account of the simple apparatus shown for the production of ultra violet rays in photo therapeutics. This company also showed a useful apparatus for obtaining a direct current when only an alternating current is available. Other apparatus for x-ray and high frequency treatment was shown, while simple and convenient apparatus for the production of ultra violet rays from a four-inch spark induction coil with a condenser was inspected by those interested in the execution of this treatment without involving cumbersome apparatus. Electric Baths were exhibited by the Electric Trading Company, 52, Leadenhall-street, E.C., the Dowsing Radiant Heating Company, Limited, 24, Budge-row, Cannon-street, E.C., and by the Sanitas Electrical Company, Limited, 7A, Soho-square, W. The last-named exhibited also a new lamp for the production of ultra violet rays. It is called the "Dermo" lamp and has iron for its terminals, giving what has now been called an iron light. Messrs. Harry W. Cox, Limited, 9, 10, and 11, Cursitor-street, Chancery-lane, E.C., showed their latest x-ray apparatus and a new improved electrolytic break. The electric current is utilised by Messrs. W. Bellack and Company, 147, Oxford-street, W., for actuating the "Muschik vibratorium," which is a rapidly-pulsating hammer which is brought in direct contact with the body, the exciting penetrating vibration stimulating the blood-flow and exercising a good effect, amongst other things, on stiff joints.

There was again a fair display of hospital sanitary appliances, Messrs. Doulton and Company's (Lambeth, S.E.) exhibit claiming, perhaps, first attention. They showed examples of a special metallo-keramic joint as applied to closets, a strong white glazed fire-clay mortuary table, white vitreous cast-iron baths (on wheels) for hospital use, bed-pan sinks, and lavatories. Messrs. George Jennings, Limited, 63 and 67, Lambeth Palace-road, S.E., showed similar examples of improved sanitary appliances adapted for general use and for hospitals and sanatoriums, &c. Their patent valves by which hot water cannot be turned on without first opening the cold valve and by which without any risk of accident to the patient any desired temperature of water can be obtained are well worth mentioning. Messrs. Defries, Limited, 146 and 147, Houndsditch, E.C., exhibited the Pasteur filter in various forms and the Equifex disinfecting and deodorising apparatus. The London Necropolis Company, 121, Westminster-bridge-road, S.E., exhibited photographs illustrating their methods of disposal of the dead and the cemetery at Brookwood, near Woking. This company undertakes the so-called "earth-to-earth" disposal in which the natural dissolution of the body is favoured by the action of the earth. Particulars were given also as to the conduct of cremation and its cost.

Disinfecting compounds were well represented, as were also special soaps. Messrs. Major, Limited, of Scullcoates, Hull, for example, showed a series of sanitary preparations comprised under the distinctive term "Eucryl," including a bath preparation, a toilet soap, an ointment, and a tooth powder. The Jeyes Sanitary Compound Company, Limited, 64, Cannon-street, E.C., exhibited their well-known Creolin compounds and Messrs. Newton, Chambers, and Co. of Thorncliffe, near Sheffield, decorated their stall with a large variety of "Izal" preparations. The feature of the exhibit of "Oowana," Limited, 205, Victoria-street, S.W., was a special toilet soap said to contain absolutely no animal matter or artificial colouring, the ingredients selected being of a specially pure description. Attention, it is stated, is also paid to the avoidance of alkaline excess without impairing the detergent power. The Berkefeld Filter Company, Limited, of 121, Oxford-street, W., submitted several examples of their new "tubor" improved germ-proof filter to the notice of the visitors.

As regards the section of special foods and drugs it may be said that this display was somewhat smaller in scale than in previous years, although very general interest was shown in the preparations of this class. We propose to deal with this section next week.

(*To be concluded.*)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8648 births and 4919 deaths were registered during the week ending May 17th. The annual rate of mortality in these towns, which had been 16·6 and 17·2 per 1000 in the two preceding weeks, further rose to 17·3 per 1000 last week. In London the death-rate was 16·2 per 1000, while it averaged 17·7 in the 75 other large towns. The lowest death-rates in these towns were 7·2 in Walthamstow, 8·3 in Hornsey, 8·0 in Warrington, 9·4 in Devonport, 10·3 in Hastings and King's Norton, 11·0 in Bournemouth, and 11·3 in Aston Manor; the highest rates were 23·5 in Bolton, 23·7 in South Shields, 23·9 in Manchester, 24·9 in St. Helens, 25·7 in Middlesbrough, 26·3 in Wigan, 26·4 in Sunderland, and 27·0 in Bootle. The 4919 deaths in these towns included 516 which were referred to the principal zymotic diseases, against 534, 489, and 519 in the three preceding weeks; of these 516 deaths 144 resulted from measles, 126 from whooping-cough, 67 from diphtheria, 51 from scarlet fever, 49 from diarrhœa, 48 from small-pox, and 31 from "fever" (principally enteric). No death from any of these diseases was registered last week in Hastings, Rotherham, or West Hartlepool; in the other towns they caused the lowest death-rates in Brighton, Portsmouth, Norwich, Wolverhampton, Derby, Birkenhead, and Halifax, and the highest rates in West Bromwich, St. Helens, Barrow-in-Furness, Sunderland, South Shields, and Gateshead. The greatest mortality from measles was recorded in Bournemouth, St. Helens, Bury, Rochdale, Barrow-in-Furness, Bradford, Sunderland, and Rhondda; from scarlet fever in West Bromwich, Smethwick, Bolton, and South Shields; from whooping-cough in Walsall, West Bromwich, Wallasey, Bootle, St. Helens, South Shields, Gateshead, and Tynemouth; from "fever" in Merthyr Tydfil; and from diarrhœa in Northampton and Merthyr Tydfil. The mortality from diphtheria showed no marked excess in any of the large towns. Of the 48 fatal cases of small-pox registered last week 37 belonged to London, six to West Ham, and one each to Tottenham, Leyton, Birmingham, Newcastle, and Hornsey. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 1515, 1442, and 1419 at the end of the three preceding weeks, had further declined to 1360 at the end of last week; 233 new cases were admitted during the week, against 367, 250, and 248 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2207, against 2188, 2222, and 2212 at the end of the three preceding weeks; 270 new cases were admitted during the week, against 283, 258, and 256 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been

315, 240, and 231 in the three preceding weeks, further declined last week to 217, and were 41 below the corrected average number. The causes of 65, or 1·3 per cent., of the deaths in the 76 *towns last* week *were not certified*, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Hull, and in 42 other smaller towns; the largest proportions of uncertified deaths were registered in Hastings, Liverpool, St. Helens, Blackpool, Sheffield, Stockton-on-Tees, Gateshead, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·6 *to* 18·1 per 1000 in the four preceding weeks, rose again to 19·4 per 1000 during the week ending May 17th, and showed an excess of 2·1 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·2 in Leith and 15·3 in Edinburgh *to* 21·6 in Glasgow and 25·0 in Perth. The 628 deaths in these towns included 25 which were referred to whooping-cough, 21 to measles, 19 to diarrhœa, four to diphtheria, four to "fever," and one to scarlet fever. In all 74 deaths resulted from these principal zymotic diseases last week, against 78 and 46 in the two preceding weeks. These 74 deaths were equal to an annual rate of 2·3 per 1000, which was 0·5 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 29, 28, and 16 in the three preceding weeks, rose again last week to 25, of which 10 occurred in Glasgow, seven in Aberdeen, and five in Edinburgh. The deaths from measles, which had been 15 and nine in the two preceding weeks, increased again to 21 last week and included six in Edinburgh, five in Paisley, four in Glasgow, three in Perth, and two in Greenock. The fatal cases of diarrhœa, which had been 17, 23, and 13 in the three preceding weeks, rose again last week to 19, of which 11 were registered in Glasgow, three in Edinburgh, and three in Dundee. The deaths from diphtheria, which had been four, four, and three in the three preceding weeks, rose again to four last week, and were all recorded in Glasgow, where two of the four fatal cases of "fever" also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 161, 138, and 113 in the three preceding weeks, numbered 114 during the week under notice, and exceeded by 13 the number in the corresponding period of last year. The causes of 15, or more than 2 per cent., of the *deaths registered in these eight towns last week were not* certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·8, 24·9, and 22·6 per 1000 in the three preceding weeks, rose again to 24·8 per 1000 during the week ending May 17th. During *the past four weeks* the death-rate has averaged 24·8 per 1000, the rates during the same period being 16·5 in London and 16·7 in Edinburgh. The 180 deaths of persons belonging to Dublin registered during the week under notice were 16 above the number recorded in the preceding week and included 13 which were referred to the principal zymotic diseases, against 10, nine, and 12 in the three preceding weeks; of these, three resulted from *measles, three from diphtheria, three from whooping-cough*, two from "fever," one from scarlet fever, and one from diarrhœa. These 13 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 2·0 in London and 2·3 in Edinburgh. The fatal cases of measles, which had been two, three, and six in the three preceding weeks, declined again last week to three. The deaths from *whooping-cough, which had been one and two in the two* preceding weeks, increased last week to three. The mortality from diphtheria also showed an excess over that recorded in recent weeks. The 180 deaths in Dublin last week included 19 of children under one year of age and 41 of persons aged upwards of 60 years; the deaths of infants were 15 below the number in the preceding week, while those of elderly persons showed a slight excess. Four *inquest cases and three deaths from* violence were registered during the week; and 64, or more than a third, of the deaths occurred in public institutions. The causes of eight, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: W. H. Norman to the *Ariadne*; G. T. Broatch to the *Caledonia*: H. T. A. Levinge to the *Calliope*; and J. Shand to the *Agincourt*. Surgeons: J. W. Craig to the *Calliope*: C. J. E. Cock to Pembroke Dockyard; and T. T. Jeans and R. H. Mornement to the *Ariadne*.

ROYAL ARMY MEDICAL CORPS.

Major F. J. Greig joins at Aldershot and is posted to the Depôt for duty. Lieutenant F. Winslow joins at Aldershot and is posted to the Cambridge Hospital for duty.

Lieutenant-Colonel E. A. H. Roe, retired list, joins at Belfast for employment with the troops there. Lieutenant-Colonel D. F. Franklin, senior medical officer in charge of the Cambridge Hospital, Aldershot, holds himself in readiness to embark for South Africa.

Colonel Henry Comerford retires on retired pay. Dated May 17th, 1902.

Lieutenant-Colonel W. S. Pratt is granted the local rank of Colonel whilst acting as Principal Medical Officer at Gibraltar. Dated March 17th, 1900.

The undermentioned officers, on having relinquished their temporary commissions for service in South Africa, are granted honorary rank in the Army, with permission to wear the uniform of the corps:—To be Honorary Major: Major H. Wright. Dated Feb. 14th, 1901.—To be Honorary Captains: Captain C. E. Douglas, dated March 27th, 1901; Captain G. G. Oakley, dated Oct. 7th, 1901; Captain C. A. McMunn, dated Nov. 18th, 1900; Captain G. Black, dated Jan. 17th, 1901; Captain S. Linton, dated Feb. 27th, 1902; Captain F. W. Grant, dated Feb. 23rd, 1901; Captain E. J. G. Berkley, dated April 9th, 1901; and Captain R. Pollock, dated Feb 16th, 1901.—To be Honorary Lieutenants: Lieutenant J. W. Smith, dated Nov. 6th, 1900; Lieutenant R. W. Michell, dated July 7th, 1901; Lieutenant J. C. Taylor, dated Dec. 21st, 1901; Lieutenant J. K. Tomory, dated August 14th, 1901; Lieutenant A. H. McDougall, dated August 22nd, 1901; Lieutenant J. C. G. Macnab, dated March 27th, 1901; and Lieutenant W. Macrae Taylor, dated Nov. 29th, 1901.

IMPERIAL YEOMANRY.

North Somerset: Surgeon-Lieutenant-Colonel J. J. Saville resigns his commission, with permission to retain his rank and to wear the uniform of the regiment on retirement.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd East Riding of Yorkshire: Surgeon-Lieutenant T. Cameron resigns his commission.

Royal Engineers (Volunteers): 1st Devonshire and Somersetshire: Surgeon-Lieutenant A. S. Wohlmann resigns his commission. Edward Gaved Stocker to be Surgeon-Lieutenant.

Rifle: 2nd Cadet Battalion the King's (Liverpool Regiment): The undermentioned officer resigns his commission: Surgeon-Lieutenant F. H. Allfrey. 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant J. Chestnutt to be Surgeon-Captain. 17th North Middlesex: F. H. Gervis to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

Bedford: Surgeon-Lieutenant-Colonel D. Thomson, 3rd Volunteer Battalion the Bedfordshire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

Bedford: Surgeon-Captain E. F. Bindloss, *from* 1st (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment, to be Surgeon-Captain, and to command under paragraph 55A Volunteer Regulations.

Seaforth and Cameron: The undermentioned gentlemen to be Surgeon-Lieutenants:—*David John Kelly and Roderick* McKenzie Grant.

SOUTH AFRICAN WAR NOTES.

Lieutenant Beatty, R.A.M.C., was reported to be slightly better on May 19th.

THE ROYAL MILITARY TOURNAMENT.

The present year will be a notable one for military spectacles and the coronation processions will, like those of the Diamond Jubilee of her late lamented Majesty Queen Victoria, serve to bring vividly before our minds the importance and vastness of our Empire. But the Royal Military Tournament has fulfilled this function, though in a smaller way, perhaps, for many years past and we trust that on this account, though not on this account alone, it will receive such support from the public as will make the tournament held in the year of the coronation of King Edward VII. a record one. Moreover, whilst the tournament serves to educate the public and encourages and develops skill at arms, the military charities may at the discretion of the Commander-in-Chief benefit greatly. Judging from the rehearsal which took place on Wednesday, May 21st, at the Agricultural Hall, Islington, and also from the programme of the following day, when His Majesty the King was present, there can be no question of the excellence of this year's tournament. There are, of course, the usual competitions of skill between the various arms, lemon-cutting, heads and posts, tent-pegging, &c., but the "displays" show several novel features. The display by the seamen of H.M.S. *Excellent*, always one of the most popular, draws forth deafening rounds of applause, while that by the Royal Marine Artillery is an exhibition of remarkable smartness and is highly appreciated by the spectators. The musical drive by the Royal Artillery, the musical Double Ride by the Royal Horse Guards, and the Display by Indian soldiers are items of the programme which are watched with keen interest, while the Historical Ride by the 2nd Provisional Regiment of Hussars, which this year takes the place of the "Pageant," is a spectacular performance quite equal to any of its predecessors.

MEDICAL AND SURGICAL AID FOR SICK AND WOUNDED OFFICERS.

The second report of the Duke of Abercorn's committee, dealing with the year 1901 from January to December, has been just issued. The fund has for its object the relief of sick and wounded officers. Of the cases which have been considered, the majority of which received assistance, 70 were in need of medical care and 77 were surgical cases. The report says: "In addition to officers of the regular army, officers of the Royal Marines, the Imperial Yeomanry and the colonial forces have again benefited by the fund. The committee has also been able to extend the advantages of the society to army nurses invalided home. Dr. Donald Hood and Mr. Morgan have continued to place their invaluable and unremitting professional services gratuitously at the disposal of the committee and the patients, and the King has marked his appreciation by conferring upon these members of the committee the Companionship of the Victorian Order. It is largely owing to their almost daily attention that it has been possible to successfully administer the business of the fund. ...... The places of Dr. Hood and Mr. Morgan were most kindly filled during August and September by Dr. A. Elliot, Dr. G. Johnston, and Mr. T. H. Kellock. ...... The assistance which the executive committee continue to receive from the hard-worked leaders of the profession in their special departments has been invaluable. These services have been freely and ungrudgingly bestowed. ...... Sir Sydney Waterlow again offered free accommodation at Cannes to cases recommended by the committee and his generous help has been of great value. Colonel J. Stacpole, C.V.O., has continued to render valuable service to the fund at Southampton and the committee is also much indebted to Lieutenant-Colonel H. Charlesworth, R.A.M.C., Lieutenant-Colonel E. J. Erskine Risk, R.A.M.C., and Captain G. B. Stanistreet, R.A.M.C." On Dec. 31st, 1901, the funds in hand did not amount to £500. Since that time they have been further depleted, and the commitee makes an earnest appeal for funds.

We are glad to see that the Director-General of the Army Medical Staff has put before his officers a proposal which has for its object the establishment of a fund for perpetuating the memory of distinguished officers of the Royal Army Medical Corps. The memorial, it is suggested, should be placed in the headquarters mess. The medical department has contributed many distinguished officers to the army and a lasting memorial to their memory is deserved.

Obituary.

WILLIAM MILLER ORD, M.D., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL.

WE deeply regret to announce the death of Dr. William Miller Ord, consulting physician to St. Thomas's Hospital, which occurred on May 14th at the Hall, Salisbury, the residence of his son, Dr. W. W. Ord.

Dr. William Miller Ord was born on Sept. 23rd, 1834, at Brixton-hill, Surrey, and was therefore in the sixty-eighth year of his age. He was the son of Mr. George Ord, F.R.C.S. Eng., who had long been in practice at Brixton. He received his education at King's College School and at St. Thomas's Hospital, and commenced his professional work as assistant to his father. His intention to enter upon general practice was, however, altered by circumstances—circumstances which enabled him to earn wide fame as a scientific physician and a clinical teacher. For it is a fact that Dr. Ord enjoyed for many years the first reputation in London as a clinical teacher. In the multiplicity of schools which the metropolis possesses a clinical teacher may be brilliant and yet not receive the due recognition of his worth and abilities. In the northern universities this does not happen. There, if a teacher be successful and attractive his fame is known far and wide; it is spread by his students and pupils. In this respect, therefore, London is at a disadvantage compared with, say, Edinburgh. The brilliancy of a man's teaching in a London school of medicine is shed on a comparatively small field. Dr. Ord suffered from this defect, if it may be so called. But that he was a clinical teacher of the first rank all who have been privileged to sit under him will readily admit, and as far as it is possible for a London teacher to earn fame in other schools than his own Dr. Ord accomplished the same. Wherein did his strength as a teacher exist? It existed in the personality of the man himself. Gifted with a most retentive memory, with the faculty of taking infinite pains in all that he undertook, and with great greed for knowledge, he was always, from his boyhood to his final retirement from active work, a hard-working student. He won many prizes at his school, he gained medals during his career at his hospital, and he won distinctions at the University of London. After a brilliant studentship at St. Thomas's Hospital which culminated in the usual house appointments, he was subsequently appointed surgical registrar and afterwards demonstrator of anatomy.

Then his father required the help of his able son to meet the demands of a large circle of patients. Dr. Ord left the hospital and went to his father's assistance, where he enjoyed that best of all trainings for a physician—viz., a large and varied general practice. Many of the ablest physicians have laid the foundations of their subsequent success as consultants in a busy general practice and Dr. Ord was one of these. But he never severed his connexion with the hospital which he was later to adorn. Notwithstanding all the calls on his time which such an occupation demanded he accepted, when it was offered to him, the chair of zoology at his old medical school, at that time situated in its temporary home in the Surrey Gardens. And he had his reward. For when the new hospital was opened in 1871 by Her Majesty Queen Victoria Dr. Ord, having previously taken the Membership of the Royal College of Physicians of London, was appointed one of the assistant physicians to St. Thomas's Hospital, and relinquishing his private practice, to the great regret of his many patients, rich and poor, he began to practise as a consultant in Upper Brook-street. Nor was consulting work long in coming to him. It will always be a marvel to those who intimately knew his private life how he found time to see the people who came to consult him at home, to attend the hospital out-patient rooms, and to prepare and to deliver his lectures on physiology, to which chair he had at about this time been appointed. Yet his punctuality at the hospital and in the lecture-room was proverbial and his lectures were models of simple clearness, showing signs of exhaustive care in their preparation.

In 1877 when he became full physician to St. Thomas's Hospital he attracted the more advanced and the deeper educated students. His method of bedside teaching was peculiarly his own. It was not based so much on the style of Hughes Bennet and Murchison, so distinctive their beds. Those who have worked in hospitals well know that patients who are suffering from affections which prevent them from doing work, such as severe burns, fractures, inoperable malignant disease, &c., are, after a short stay in a hospital, sent on to one of the infirmaries; in fact, it is well known that the infirmaries are obliged to take in destitute cases which the hospital resident staff do not wish to keep; in other words, the hospitals are not large enough or sufficiently numerous to do the work which they should do; the hospitals, which are supported almost entirely by voluntary contributions, are quite unable to cope with the sick poor, and the infirmaries, supported out of the rates, have to come to their aid. Now the infirmaries have nearly all migrated from the centre to the outskirts of the metropolis. They have receiving-rooms and wards in the midst of the city and large buildings on the outskirts, and they convey their patients from the one to the other just as I have suggested the hospitals will soon have to convey their patients. Surely it is time to amalgamate hospitals and infirmaries. Let us still have our hospitals each keeping to its traditions but rebuilt on a much larger scale in the outskirts of London, and let each receive a certain proportion of the rates from the district of London which it serves. Will the public withhold voluntary contributions because the hospitals have migrated and are aided by the rates? I believe that the public will support them more freely than is the case now when it is realised that their scope has enlarged so greatly. As regards out-patients proper, it has been urged that hospitals have no right to treat those who are destitute and that these people should obtain Poor-law outdoor relief. Many of us know how very inadequate this system of relief is. How much better would it be if all these pauper cases were to receive the necessary medical and surgical treatment at our hospitals aided by the rates as here proposed?

But the matter must be looked at also from the point of view of medical education and it is here that one of the real difficulties in removing the hospitals seems to lie. In the first place, I think that it must be accepted that those who wish to receive a medical education must go to the places where the sick poor are, and not expect the poor to come to them from afar off. The same must be said of the physicians and surgeons who are attached to the hospitals and who have to teach the students. At the present time a student rarely enters the wards or out-patient department until he has passed his second examination—namely, the examination in anatomy and physiology of the university or examining board as the case may be. This being so, each hospital on the outskirts of the city would have a residential college attached to it and here the clerks, dressers, and resident staff would live. Then it would be necessary to have a resident physician and a resident surgeon who would be the two junior members of the staff or, at any rate, the two next to be elected on the honorary staff. The question of the attendance of the members of the honorary staff offers another difficulty. The out-patient staff would attend one day a week and see and demonstrate upon the cases of interest, the others being attended to by the resident officers. Then the in-patient physicians and surgeons would also each devote one afternoon a week to operating and to visiting and leave their cases very much in the hands of the senior resident physician and surgeon respectively. All this, of course, sounds impossible at the present day, but we must realise that with "tubes," light railways, and motor-cars the process of getting out of the city will be quite different from what it is now and we shall be able to get from the centre of London to its outskirts in one-fourth of the time which it is now necessary to expend. The two senior physicians and surgeons would, perhaps, be relieved from hospital work and would give clinical lectures and demonstrations in the receiving-rooms in the city only, and cases for them to lecture upon would be sent up in ambulances, horse or motor.

Perhaps the greatest difficulty of all in the realisation of such a scheme as above presented is the question of money. I would not for one moment suggest that all the hospitals should be under one controlling body or that they should all be managed in exactly the same manner. Each would still have its own committee or board and there should be that same system of rivalry as now exists in each one doing its utmost to excel. Without wholesome rivalry there can be no advance in medical and surgical art and practice. Nor would I suggest, as some have done, that the honorary staff should receive payment for their work. The work which the visiting physicians and surgeons perform in hospitals could not be adequately paid for, and, of course, partial payment is out of the question. A most strict inquiry system would have to be adopted in each hospital so as to insure that none but patients unable to pay a private medical man were admitted. I only wish that such a system were generally adopted in all the existing general hospitals. A few of them have proved that it can be done, not perfectly perhaps, but nearly so. As our general hospitals are now situated there seems no possibility of preventing the absurdly large amount of double work which is being carried on by the Poor-law infirmaries and by the hospitals, but if the latter were once removed to the outskirts of London—a few wards being kept for casualties in the city—there might be at any rate some hope of combination in the future.

I am, Sirs, yours faithfully,
PEYTON T. B. BEALE, F.R.C.S. Eng.

March 29th, 1902.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—I have read with interest your notice of the Calliano belt for sea-sickness in THE LANCET of Feb. 15th, p. 459, and I am reminded that there is comparatively little published about this distressing and common complaint. During 15 years I have had experience in all sorts and conditions of boats—huge Atlantic liners and small tramp steamers, 30-knot "catchers" and torpedo-boats, and yachts of all degrees, from ocean cruisers to racing machines. On all these designs sea-sickness, like "*corroding care,*" steps aboard and refuses to be left behind.

I do not wish to disparage the Calliano belt—it may in some cases give relief, but I cannot believe in any such mechanical contrivance as being a cure for sea-sickness, the origin of which is a disturbance of the nervous system. Vomiting is by no means its worst symptom—indeed, those who vomit early and without much effort are usually the first to recover—but there are many cases of intense vertigo and giddiness and sometimes alarming syncope where sickness is quite subordinate. In these instances patients will explain that they feel as though the whole earth was sinking away from them and then experience the terrible feeling of falling through space. A Scotsman once put it vividly to me that he would "cling mother-naked to a whin- (gorse-) bush for support."

Many inventions and much money have been brought to bear on the prevention and cure of sea-sickness, but hitherto without any enduring benefit, and unless treatment is directed to the central nervous system I do not think that any is ever likely to accrue. I take it that it is the inability of this system to adapt itself to its surroundings which is the primary cause of the complaint. Vomiting follows from reflex action on the abdominal organs, causing an excessive flow of bile, intestinal, and gastric secretions. But vomiting is only a symptom; more important though less obtrusive symptoms in arriving at the origin of the complaint are coldness of the extremities from diminished peripheral circulation and the faintness and giddiness already referred to which point to an anæmic condition of the brain. Further proof of nervous origin may be found in the effect that strong emotions have on sea-sickness. In this respect intense fear is the emotion brought into play beyond all others. The imminent danger of shipwreck has a most extraordinary effect in arousing the torpid and apparently almost lifeless sufferer to a state of energy that no known medical treatment can compete with. News of great joy it has not until recently been possible to receive at sea, but with Marconi's wireless telegraphy the prostrate passenger with miles of tossing waves still separating him from dry land may now receive a message to inform him of sudden fame or fortune and straightway leave his berth and walk the quarter-deck. Hitherto it has only been my fortune or misfortune to see the results of fear, and this, though generally imaginary, I have frequently seen to arrest suddenly the course of sea-sickness. The writer once experienced this sensation in his own person when he was not as now, from long practice, immune from the nauseating effects of rough seas. After an attack of typhoid fever he was convalescing on a steam yacht in the Mediterranean when phlebitis supervened in the right leg, followed by a blocked femoral vein and possibly external iliac too. After keeping the yacht for a month in harbour he felt so acutely the disappointment of others on board that he

of Edinburgh teaching, as on the model of the Paris schools. The report of a case having been read out by one of his clinical clerks Dr. Ord would, after verifying or correcting the physical signs, give a clear and concise verbal picture of the patient's condition, he would predict the possible complications which might occur, and would give his reasons for every remedy which he proposed to employ. And withal his diction was so polished and his store of information was so vast that he would charm the students who came to his wards from Oxford and Cambridge by his classical methods and language, at the same time impressing all with his clinical acumen and knowledge. Dr. Ord's gift of clear and eloquent exposition doubtless came to him as the result of his accurate practical work. He had a first-hand experience of the difficulties that beset the path of the student and knew in what direction they required removal. How hard he worked at the microscope in his endeavours to elucidate the varying forms which urinary crystalline bodies may assume in the presence of colloidal or other media he has himself recorded. How he studied minute points in pathological anatomy, and made his students study them also, all those who worked under him will remember. For Dr. Ord the microscope was an aid to diagnosis and the treatment of his patient rather than for the verifying of a diagnosis after death. Much as the profession owes to Gull for the discovery of the disease known as myxœdema it still remained for Dr. Ord to work out the pathology, to fill in the picture of signs and symptoms, and finally to give it the stamp of nomenclature. And his painstaking work deserved the recognition that it has everywhere received.

But besides being an able physician and teacher Dr. Ord was a man of the broadest education. As a classical scholar he could hold his own. His knowledge of English literature embraced the writings of the earlier English dramatists and of the great compilers of British naval and military history He was familiar with every plant in the field, common, or hedgerow, and he had a close grasp of geology, as well as of the laws governing the forces of nature.

Personally, he was the warmest of friends and a most genial acquaintance. His generosity, too, so long as he knew that there was real distress, did not stop at the placing of his great skill at the disposal of the sick, but he gave freely from his purse. "Many have been the weekly doles which I have seen him bestow on people who though poor had no other legitimate claim on his benefactions" writes one of Dr. Ord's colleagues to us, and his experience is the same as our own. Though it may probably be said that no single man is necessary in our great profession, yet it will be felt by most of us that William Miller Ord's death has left a gap which will take many years to fill.

Dr. Ord was twice married, and his second wife survives him. He leaves one son, Dr. W. W. Ord, and four daughters.

JAMES SCARBOROUGH LOE, M.R.C.S. ENG., L.S.A.

MR. J. S. LOE, who died at his residence in Chapeltown-road, Leeds, on April 20th, had held for a great many years a very prominent position in that city. He was born at Stony Stratford, Buckinghamshire, and when six years old was taken to Leeds where his father was a well-known medical man. Having resolved to follow his father's profession Mr. Loe studied both in the Leeds School of Medicine and at Guy's Hospital, obtaining the diploma of L.S.A. in 1852 and that of M.R.C.S. Eng. in 1853 His professional life, therefore, covered a period of nearly 50 years, the whole of which was spent in Leeds, where he had a large practice and held several public appointments, including those of medical officer to one of the Poor-law districts, surgeon to the town mission, and honorary surgeon to the fever hospital. Mr. Loe took an active part in municipal life and both as a city councillor and an alderman his professional knowledge enabled him to render important public services when chairman of the City Hospitals Committee and deputy chairman of the Sanitary Committee. In the former capacity he was the means of effecting great improvements in the infectious diseases hospital and he was a warm supporter of the scheme for providing adequate hospital accommodation at Manston, together with a small-pox hospital at Killingbeck. Mr. Loe had a long connexion with the volunteer force. He entered the Leeds Rifle Corps as a private in February, 1860, before the regiment had completed the first year of its existence, so that he had little short of 40 years' service when he retired in 1899 with the rank of brigade-surgeon-lieutenant-colonel. The deceased, who was in his seventy-first year, was twice married and has left a widow.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced :—Dr. Julius Bruck, Professor of Odontology in the University of Breslau, at the age of 61 years.—Dr. Hans von Hebra, Extraordinary Professor of Dermatology in Vienna and son of the distinguished dermatologist. He was president of the Austrian Temperance Society and had of late years interested himself considerably in questions of municipal hygiene.—Dr. Johann Habart, a well-known Austrian military surgeon whose experiments on small-bore rifle wounds have attracted considerable attention.—Dr. Voskresenski, *privat-docent* of Midwifery in Kieff.—Dr. F. Fusci, Professor of Surgical Anatomy in Naples.—Dr. Theodor Rompler, author of several works on phthisis.—Dr. Florian Beely, a well-known Berlin orthopædic surgeon, at the age of 56 years.—Dr. Möller, chief medical officer of the Danish army—Dr. Friedrich Leopold Goltz, the well-known Strasburg physiologist. He was born in Posen in 1834, and after studying medicine in Konigsberg taught physiology there and at Halle until the foundation of the German University of Strasburg, when he was selected for the chair of Physiology, which he filled until little more than a year ago, when he was obliged to retire on account of failing health. His researches on the functions of the brain and spinal cord are well known in all countries.—Dr. Meredith Clymer, formerly Professor of Nervous Diseases at the Albany Medical College.—Dr. N. Kalindero of Bucharest, foreign correspondent of the Paris Academy of Medicine.—Dr. F. Trautmann, Extraordinary Professor of Otology in Berlin.

"Audi alteram partem."

REMOVAL OF SMALL-POX PATIENTS.

To the Editors of THE LANCET.

SIRS,—With reference to your annotation on page 1335 in your issue of May 10th, *re* removal of small-pox patients, an inaccuracy appears in the second line of the first paragraph. The conviction of Quelch did not take place until May 10th and not on May 2nd as stated. The divisional court was moved to quash by *certiorari* the justice's order to remove Quelch to the small-pox hospital, which order was granted on application before Mr. T. F. Jones, one of the justices for Surrey. A short statement of the *facts* of the case is that on March 2nd I was asked to see the first case in consultation with *Dr. Graham Morris* of Wallington, on which date I was unable definitely to say whether Quelch was suffering from small-pox or not On the following day I saw him early in the morning and found it to be a well-marked case. In consequence of the refusal to allow the patient to be moved I was obliged to obtain a justice's order. It was after this that Mr. T. R. Allinson saw the patient I would point out that my contention that the house was *not suitable for the* treatment of small-pox cases was justified by the fact that a fortnight later the father contracted small-pox.

I am, Sirs, yours faithfully,
C. M. FEGEN,
Medical Officer of Health.

Croydon, May 13th, 1902.

LARGE DOSES OF STRYCHNINE IN SURGICAL SHOCK.

To the Editors of THE LANCET.

SIRS,—Dr. Gordon Sharp's single case is of interest in showing the possibilities as opposed to the probabilities of large doses of strychnine in surgical shock. The favourable results of large doses of strychnine having been thoroughly established by many independent observers, surgeons who have had repeated personal experiences of these results are not likely to be deterred by occasional cases such as that of Dr. Sharp from giving a collapsed patient the chance of life which strychnine given in ultra-pharmacopœial doses can alone afford. To allow a patient to die from shock without the chance of recovery obtainable from large doses of strychnine, because such doses had in rare instances produced severe spasms, would be about as reasonable as to decline to open the abdomen of a patient dying from internal hæmorrhage because operation had failed to save every case and had occasionally even expedited the fatal issue.

I am, Sirs, yours faithfully,
Plymouth, May 18th, 1902. C. HAMILTON WHITEFORD.

LEFT-OFF CLOTHING FOR OUR SOLDIERS.

To the Editors of THE LANCET.

SIRS,—May I again appeal through your columns for left-off clothes for soldiers as the stock is about exhausted? Through the generous response to my last appeal we have been able to provide clothing for over 300 who have returned from the war without which they would have been unable to obtain employment, and the number of men returning is on the increase and will no doubt be so for some time.

Parcels should be sent to Captain Holmes, 70, Victoria-street, S.W., who will acknowledge their receipt.

I am, Sirs, yours faithfully,
HERBERT F. EATON, Major-General,
May 20th, 1902. Chairman Soldiers and Sailors' Help Society.

WHAT IS SCROFULA?

To the Editors of THE LANCET.

SIRS,—In the "Revised Classification of Causes of Death in the National Records," published in THE LANCET of May 10th, 1902, p. 1340, for the guidance of medical practitioners I notice among general diseases the antiquated term "scrofula." It would be interesting to learn from Dr. John Tatham, under whose sanction the above list has appeared, what is meant by this term, how it can be regarded as a cause of death, and why, as it has now become obsolete, the term should have been retained in a classification purporting to be official and authoritative.

I am, Sirs, yours faithfully,
May 19th, 1902. PES.

ERRATUM.—In the letter from Mr. F. Bolton Carter published in THE LANCET of May 17th, 1902, p. 1427, under the heading "Large Doses of Strychnine in Surgical Shock," the writer was made to say that the largest dose given without any after-symptoms was 30 minims during an operation for perforated gastric ulcer, the patient recovering. The number should have been 50, not 30; the error was ours.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—Changes of Policy with Results in Bombay City.—Prayers by Hindoos in Calcutta to stop the Plague.—The Latest Famine Returns.

A DECIDED improvement is shown in this week's plague mortality. The total for the whole of India has declined from 24,380 to 19,419 and the diminution is general. The Punjab still continues to be the most affected area. The figures just published for the past week are: Bombay city, 658 deaths against 696; Bombay Presidency, 2045 against 2093; Karachi, 136 against 137; Madras Presidency, 60; Calcutta, 588 against 603; Bengal, 760 against 925; the United Provinces, 773; the Punjab, 14,145 against 16,281; Mysore, 131; Rajputana, 37; and Berar, 79. The disease seems to be at its worst in Karachi and is commencing the down grade in Calcutta and Bombay. Another case has been imported into Rangoon but so far the disease has not spread.

The report of the municipal commissioner for Bombay during the year ending May 31st, 1901, shows the effects of changes in plague administration. All compulsory measures for that year except for disinfection were withdrawn. The health camps were continued but admission was voluntary. The features to be noted are that the mortality from plague showed a considerable increase and that inoculation was much less resorted to. The increase of plague may not have been due to alterations in plague measures, but the decline of inoculation from 150,000 in 1900 to 7000 in 1901 must certainly be ascribed to the changed policy. There was a large decrease of persons admitted to the health camps. On the other hand, it is said that concealment of cases was much less resorted to and that a better feeling existed amongst the people. It is argued also that a larger proportion of cases came under notice. Lastly (and this is apparently a great point), there was a very considerable saving in expenditure.

To illustrate native views of the plague it may be mentioned that the Hindoos of Calcutta have fixed upon May 26th for a special *puja* to be offered to the goddess Kali to propitiate her and to pray for her intervention to stop the plague. There will be chanting of humiliatory and supplicatory hymns for six hours—from six to midnight. An enormous congregation is expected to the famous shrine. I have not heard of any other steps being taken by the native community to assist in the control of plague and disinfection of premises is now the one and only measure adopted by the authorities. The natural course of an outbreak of plague can be well studied in Calcutta and Bombay city where it is now showing a clinical course undisturbed by treatment.

The famine returns still indicate widespread distress. There are now 370,000 persons under relief.

April 25th.

PLAGUE PRECAUTIONS AT MARSEILLES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

A Visit to the Quarantine Island of Frioul.—The Modern and Improved Disinfecting Station.—Infected Bones from Bombay.—How the Passengers and Crews are Disinfected.—An Admirable Establishment Insufficiently Manned.—Savants in Quarantine.

ON the port sanitary authorities of Marseilles rests a heavy responsibility. Marseilles has often been described as the door of the East and to-day, from the East, plague-stricken ships make for the port of Marseilles. If the danger of this traffic was occasioned only by human beings it would be comparatively easy to take precautions giving a good prospect of success, but there is also the merchandise and, worse still, there are the rats. In one respect, however, Marseilles is fortunately situated. There are islands a few miles out at sea where there are good anchorage and shelter for ships and where quarantine and disinfection can be carried out at a safe distance from the port. For this purpose the island of Frioul was selected many years ago and time enough has elapsed for this quarantine station to acquire an unenviable notoriety. But to-day more intelligent methods are applied and the complaints are not so frequent. Some 15 years have elapsed since last I visited this quarantine station and I am now able to bear witness to very great improvements. When last I was at Frioul the chief structure consisted of a broad and lofty shanty. Within its bare walls there stood a number of counters or tables. On these tables merchandise, bales of rags, and the like, taken from ships were spread out. Under the tables a certain amount of sulphur was burnt. The shed was so large and the crevices were so numerous that the fumes soon became diffused throughout the surrounding space and escaped. It was found that the fumigation even failed to kill the fleas. Yet this was called disinfection. All is altered now and the fear of plague has very materially contributed to the improvements effected. As a suitable beginning it may first be noted that a landing-stage has been built. Though it is but a rough and hastily-erected structure it greatly facilitates the loading and unloading of ships. Down the centre of this jetty there is a high wooden palisade. On one side of this barrier the infected goods are landed and on the other side they are placed on board the steam launches and barges that convey them back to the ships at anchor after they have been disinfected. A Decauville narrow-gauge railway line has been laid on each side of this partition and it saves much labour and loss of time. One line leads into the disinfecting station; the other line starts from the back and the outside of the station and takes the disinfected goods back to the pier, but before reaching this landing-stage there is a third line, a loop line which goes to a great storehouse or dock where the goods can be stored for some time.

Thus a ship need not wait at Frioul till its cargo has been disinfected but can proceed to Marseilles and land its passengers and the goods can be safely stored till such time as it may be convenient to remove them.

A more rational process of disinfection is now practised. Fumigations are carried out on board ship where an accurate estimate of the cubic space to be dealt with can be obtained. The rule is to burn 20 grammes of sulphur per cubic metre. On shore there are two sorts of disinfection practised—that which is applied only to the outside of boxes, bales, and cases, and the through-and-through disinfection of body-linen, clothes that have been worn on the journey, bedding, &c. For the former process a very ingenious system of hydrants has been established. At the further end of the disinfecting station there is an engine-room. Here there is a cistern filled with a solution of creolin. A pump is attached and worked by the engine. The disinfecting solution is pumped into a copper cylinder which will stand a considerable pressure and the disinfectant is forced along the pipes to the hydrants. There are a number of these hydrants in the largest disinfecting room which are placed at a distance of a few feet from each other. To these a flexible hose is affixed. The nozzles are so arranged as to produce a fine spray and with this the disinfectors play upon the goods exposed, just as a fireman plays with water upon a fire. But as the amount of disinfecting fluid and the number of hydrants in use vary from time to time, while the engine continues pumping at the same rate, an explosion from over-pressure might occur. To meet this a safety-valve has been cleverly contrived by which when the pressure is too great an aperture is forced open and the disinfectant is poured back into the cistern instead of being propelled along the pipes to the hydrants. Thus the system is worked automatically and there is no need of skilled labour to watch over this machinery.

Apart from these hydrants there are a number of the portable spray-producers of the type which is known as the "Dose-métric Mélangeur Laurens." This is a hand-pump that can be wheeled along or lifted and carried by two men. It can thus be conveyed on board a ship or to any place where it may be needed and which is beyond the reach of the hydrants. The proportion of disinfectant mixed with the water used is automatically regulated and the apparatus can therefore be worked by an unskilled attendant and the required dose will be mechanically supplied with mathematical precision. The pressure can be obtained to produce the spray by turning a wheel, or simply by water-pressure if there is a water-main sufficiently near at hand to establish a connexion. This system of disinfection was first applied to some 2000 tons of broken bones imported from Bombay. These are the bones of small young cows held sacred by the Hindoos but exported by Mahomedans, and they often come from plague-infected districts. Many of these bones are forwarded to Lyons where the gelatin is extracted and *noir animal* is manufactured for the sugar refineries and for the making of wax. It was thought that such bones might convey the germs of plague, particularly if they were overrun by rats; hence the care which is taken to disinfect them with a spray delivered with great force and so finely subdivided that it spreads itself all over the bones

When a ship arrives from a country where plague or yellow fever prevails it must stop at Frioul. The passengers are then medically and very carefully examined. The chief danger is with the natives—Indians, Lascars, and others—and they are made to strip. On one recent occasion, though it was thought that everyone on board was in good health, two natives were found with buboes due to plague infection. In such a case—that is, when there is actually plague on board—10 days of quarantine are imposed. If, on the other hand, there is no illness of this description on board, all the linen that has not been disinfected during the journey is, according to the now well-established rule, removed from the ships. But as nearly all the ships carry disinfecting stoves it is only such personal table- and bed-linen as has been quite recently in use that has to be landed at Frioul and there disinfected. Without waiting for the conclusion of this operation the ship may be allowed to proceed to Marseilles with at least its first-class passengers who may land on arriving More rigour is displayed towards emigrants and steerage passengers generally.

Starting from the landing-stage the little railway line penetrates the first and largest compartment of the disinfecting station. Here merchandise and passengers' luggage are placed on counters and played upon with the disinfecting spray from the hydrants. The trucks that are loaded with the bedding, mattresses, table-linen, and body-linen travel further on to another and smaller compartment. Coming through the wall of this compartment there are four disinfecting stoves, two Blanc stoves, and two Geneste and Herscher stoves. The former are larger and better suited for mattresses and cumbersome articles. The stoves, of course, open at both ends. One end is on the infected side where the goods are inserted, and they are withdrawn on the other side of the wall and at the other end of the stove after they have been disinfected. Here another line with other non-infected trucks serves to convey the purified bedding, &c., back to the landing-stage. The disinfection is produced by steam under pressure which is occasionally discharged so as to secure the penetration and even distribution of the heat inside the mattresses. Each stove is fitted with what is described in slang but graphic parlance as a *mouchard*. This is a thermometer that records the internal temperature of the stove on a drum that revolves by clockwork. The director keeps in his pocket the key of this detective, which gives in a tracing a record setting forth how long each operation has lasted and to what amount of heat and what fluctuations of heat the disinfected articles have been exposed. This is a very valuable method of control and it dispenses with the necessity of constant personal supervision. It obviates, also, all errors While luggage and bedding are thus being disinfected the passengers and crew are led to another department. Here there are 20 compartments, each having three subdivisions made of corrugated iron partitions. These compartments consist first of a little cabin where there is a seat and here the person to be disinfected takes off all his clothes, makes a bundle of them, and affixes thereto a metallic number that has been given to him. The bundle is at once taken off to the disinfecting stove. The passenger or sailor then enters the second or central portion or cabin. Here he finds some soap and on pulling a string, receives a warm or a tepid douche. After he has thoroughly washed himself he proceeds to the third subdivision of his compartment where he finds a wrap, dries himself, and awaits the arrival of his bundle of clothes, which is brought to him from the stove after it has been disinfected. He then goes out from the opposite side to that by which he entered and either returns to his ship or, if he is to be detained, proceeds to the quarantine quarters Still further on there are other compartments where instead of douches there are warm baths and one of these is most luxuriously fitted up. Sometimes as many as 250 passengers have thus been disinfected in one morning, taking 20 at a time, the operation lasting about a quarter of an hour for each person. Passenger ships arriving at seven in the morning can very generally start for Marseilles by noon. But if there are many immigrants these are sent on to Marseilles later in the day by tugboats, while the mail-steamer leaves earlier with its first-class passengers. If the ship is suspected disinfectants are poured into all the dirty places. Sulphate of copper is used where the cattle have been and it is put down the drains.

The disinfecting station is an oblong building divided longitudinally, the right portion on entering being the infected side and the left being the disinfected side. In the partition wall glass panes—not windows that can be opened—have been fitted at different intervals, so that it is possible to see through without coming into contact with infected things or persons. Consequently, the disinfectors can be watched from the safe side while they are at work, and there is telephonic communication throughout. At the furthest end there is the engine-room where a considerable amount of work has to be done. There is the pumping of the disinfectant solution to supply the hydrants already described. Then there are the boilers to warm the water for the douches. This warm water and also cold water from the cistern outside have to be pumped up into large tanks overhead so that they may be delivered by gravitation wherever they are required. As the only supply is that of the rain-water, which is collected in a large underground system, this is apt to fall short, especially when there is much work to be done. Consequently an apparatus for the distilling of sea-water has been fitted up in the engine-room to make up for this deficiency Then just outside the engine room, but in the infected part of the building, there is a trough which has to be supplied with boiling water and here linen stained with pus or blood is soaked before it is put inside the stove.

If this were not done the linen would be stained and spoilt. For the stoves, engines, &c., full printed instructions are posted on the walls which are very useful when extra and inexperienced workers have to be engaged. On the day of my visit *La Provence* had just arrived from Buenos Ayres. There were 448 passengers on board and of these only 57 travelled first or second class. The rest consisted, for the most part, of disappointed Italian emigrants returning home. The ship had left eight days before cases of plague were reported from Buenos Ayres. The rule stipulates for 10 days and therefore, some precautions were taken. Through the glass partitions I saw some of the mattresses arrive and, plague or no plague, it seemed to me a very good thing that they should be disinfected. They were very filthy, which is not surprising considering the class of persons who had used them.

In all its details, by reason of the precautions enforced, the ample space devoted to the purpose, the ingenious mechanical appliances employed, and the care taken to disinfect the persons and the clothes of the passengers and the crews, and of the disinfectors themselves, this establishment commends itself to all who are interested in such matters and especially to port sanitary authorities. So far as the structure is concerned and the manner in which it has been planned the authorities are to be congratulated and it would be difficult to suggest any improvement. In thus expressing so favourable an opinion I am but repeating what Professor Koch of Berlin said when last he visited Frioul. There is, however, a weak side The staff of assistants is absolutely insufficient. It consists for the most part of old men who are paid only £36 a year. For this small sum they must live with their families a dull isolated life on the island. It is true that their wives get a little washing to do and that this adds to their income, but still they are so poor that it cannot be a matter of surprise if they occasionally accept bribes. When they are sent on board a ship to fetch away linen or luggage to be disinfected they may be bribed to leave certain objects behind them or, to oblige passengers who are in a hurry, they may stamp luggage before it has been disinfected so as to get it through more rapidly. Consequently it may happen that "suspects" are not watched strictly enough. When, however, it is not merely a question of suspicion but there is positive danger all the superior officers are on the spot, the underpaid attendants are carefully watched, and the precautions deemed necessary are enforced with great rigour. Even if all the attendants were properly paid difficulties would still arise in consequence of the great irregularity of the work that has to be done. Sometimes there is absolutely nothing to do, while at other times it is necessary to employ a great number of extra hands and these are very difficult to obtain.

The most notable case in point was that of the ship *Sénégal*, which gave rise to a somewhat acrimonious debate in the French Academy of Medicine. The *Revue Générale des Sciences* had organised a pleasure cruise in the Mediterranean and 174 passengers embarked at Marseilles on Sept. 14th, 1901. Their ship, the *Sénégal*, had arrived at Marseilles on August 28th, coming from Alexandria where cases of plague had been notified. According to Article 5 of the international agreement the passengers and crew were carefully examined and were all found to be in good health. The linen, bedding, luggage, &c., were disinfected. Events proved that this did not suffice, for, with all these precautions, no account was taken of the rats. Four days after the *Sénégal* had left Marseilles with its distinguished passengers on board, and after visiting Ajaccio, one of the crew fell ill with plague. The ship at once returned to Marseilles and landed its passengers at Frioul. Now the number of first-class passengers detained at Frioul during the 10 years from 1891 to 1900 only amounted in all to 119. But here, in one single day, there came 174 passengers all clamouring for first-class accommodation. An ex-Cabinet Minister, leading men of science, and other influential and distinguished persons composed this very exceptional body of travellers. The confusion, the inconvenience, and even the hardships that ensued were graphically described in various papers and by one of the victims, Dr. Bucquoy, at the Academy of Medicine. Though every effort was made to reinforce the staff it was impossible to obtain sufficient attendants. Nor were those who did volunteer for this service at all competent. To extemporise a large hotel staff is no easy matter, particularly when each person who volunteers conceives that he is incurring the risk of contracting plague. When the *Sénégal* arrived at Frioul there were but eight attendants besides the medical staff. 18 others were immediately engaged. But this was insufficient. There were not hands enough to carry the personal luggage from the disinfecting station to the dwelling-houses which are situated at a considerable distance. Many essential necessaries were wanting. On listening to these many complaints it occurred to me that the staff of a quarantine station such as that at Frioul should be recruited much on the same principle as the British army. Men should be engaged, sent to Frioul for a few months, and after having been thoroughly instructed they should be drafted into a reserve corps. A small retaining fee or pension should be paid to them on the understanding that they should hold themselves ready to resume active service for full pay whenever they were called upon. In this manner and in the course of time a competent and numerous reserve would be at the disposal of the sanitary authorities. Nevertheless, though this does not exist at present, I feel it only fair in regard to this controversy to quote the concluding passage of the speech delivered at the Academy of Medicine in reply to Dr. Bucquoy by M. Henri Monod, Councillor of State and Chief of the Sanitary Department of the Ministry of the Interior. M. Monod said: "A second fact, to which M. Bucquoy has not alluded, is worthy of the attention of the Academy. Let us turn our eyes away from the arid rock of Frioul and look towards France. We sympathise, as we are bound to do, with the annoyances endured by the very distinguished passengers of the *Sénégal*, but as no one of them suffered in health we may without hardness of heart view the question in its more general aspect. For more than five years and a half we have been threatened with the plague and this menace increases with formidable rapidity. The number of ships coming from plague-stricken countries and entering French ports amounted to 11 in 1896, to 80 in 1897, to 209 in 1898, to 368 in 1899, and to 655 in 1900. In all there were 1348 ships and of these 801 arrived at Marseilles. During these five years our sanitary services, and especially that of Marseilles, were face to face with a new and alarming peril, for the modern achievements of science are so far uncertain that they have not sufficed to efface the terrible recollections of the past. The plague seems to have established itself in Egypt. There has been plague in Portugal. There have been cases of plague in Italy, some cases in Scotland, others in England; up to the present moment there has not been a single case on French territory. This is a fact which we must bear in mind; it is without precedent; and this entitles many of our agents, but more especially Dr. Catalan (the port medical officer of Marseilles), to receive the expression of public gratitude."

But the precautions taken and thus publicly and gratefully acknowledged are now admitted to be insufficient, and this in spite of their so far successful effect. The danger is with the rats and new and important measures are now enforced to meet this risk. They will form the subject-matter of my next contribution.

(To be continued.)

BIRMINGHAM.

(From our own Correspondent.)

A Question of Labels.

THE distribution of medicine to out-patients at hospitals and dispensaries is a matter of routine that is generally carried out with a proper sense of responsibility. But errors will sometimes happen and a patient gets the wrong medicine or mistakes the directions given to him concerning it. The wonder is that in the circumstances mistakes are so few and that so little harm is done. It has lately been suggested that the name of each patient should be written upon the label affixed to his bottle. But this would entail an amount of labour of which the author of the suggestion probably knows nothing and the reform would not always prove successful, for bottles, names, and patients might afterwards get mixed. A patient at a local dispensary lately complained, he and his wife being recipients of medicine, that no names were placed upon the labels. The man drank the wife's medicine and the wife took that from the husband's bottle, fortunately without ill results to either. As a rule it is the plan for the patient to take his prescription to dispensary where it is made up and handed to him. The ponsibility of remembering its appearance so as to be le to identify it thus remains with him. Bottles contain- poison are always prominently labeled as such and the nted directions for dosage, &c., ought to be sufficient en the medicine is handed directly to each individual lent. It is evident that no other sort of directions can be en to hospital and dispensary patients, for time would allow of their being written. At a certain hospital ently *marking-ink was administered instead of meat-juice* wo scarlet fever patients. On investigation the committee nd that a bottle similar in shape to that used for meat-juice been in use for nine months as a receptacle for marking-ink. iously this was a gross indiscretion and it was recognised the committee in the proper condemnation and punish- *t of the offenders.* But *if hospital nurses* can make such mistakes how much more liable to do so must out-patients at hospitals and dispensaries be.

Midland Counties Asylum.

Formerly known as the Midland Counties Idiots Asylum this institution continues its usefulness and activity. Lord Leigh presided at the thirty-fifth annual meeting of the subscribers on April 25th. The report showed that during the past year the admissions were 12 in number, the average age not being over nine years. In dealing with the feeble-minded one difficulty of the committee had always been the inability to get the patients sufficiently young. The provisions in the United Kingdom generally for the education of such children were stated by the report to be totally inadequate. The committee consider that owing to the want of proper facilities thousands of poor children are unable to receive treatment in special institutions. A shoemaker's, a tailor's, and a carpenter's shop have been fitted up at the institution and an appeal is being made for more funds, the advantages of technical training being pointed out. It is, of course, now generally recognised that the feeble-minded when taken in hand while young are capable of improvement and that many, if taken in time, may be saved from drifting into lunatic asylums or prisons.

Sanitation and Cookery.

The Birmingham Ladies' Association for Useful Work have set themselves a laudable programme. For 30 years they have been endeavouring to inculcate the principles of sanitation in the poorer parts of the city. They are now providing *for the teaching of cookery in the slums.* Whether this teaching will be received in the same spirit with which it is being offered remains to be seen when the experiment has been sufficiently tried. The provision of lady sanitary inspectors in different districts of the city has made the work of the society less urgent from this point of view. Yet there is *still abundant room for the exercise of thrift and knowledge* in the ordinary transactions of domestic life among the lowest stratum of our society.

May 20th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Mersey and Irwell Joint Committee.

DURING the last 10 years much has been done to prevent the streams in the watershed of the Mersey and the Irwell from becoming fouler. In many cases great improvement has been made but much more must take place before sea-trout and salmon frequent these rivers as of yore. In his annual report of the work done by the joint committee Mr. A. Tutton, the chief inspector, gives some facts showing the great extent of its jurisdiction, consisting as it does of seven county boroughs, 14 non-county boroughs, 61 urban district councils, and 12 rural district councils, with a total population of 2,456,723 and a rateable value of £11,986,609 On the rivers Irwell and Roach there are 285 manufactories; on the Irk, once known for its excellent trout-fishing, 46; on the Medlock, 15; and on the Mersey, 99—a total of 445. Into all these streams the manufacturers used to throw, or allowed to be washed in, their waste ashes as a matter of course, but there have been no serious cases of pollution by solid matter during the past two years, though action has been taken in several small cases. In 1892 26 urban authorities had no scheme for preventing pollution, but now all except one urban authority and two rural authorities have such a scheme. The biological filter method of treatment is being adopted more and more and is of great value where suitable land cannot be obtained, though Mr. Tutton thinks that it can never take the place of first-rate land treatment as far as efficiency is concerned. Manufacturers *now generally recognise the necessity* for, and the justice of, treating their trade waste, and legal proceedings have not been required for four years. The result of all this is that considerable improvement in the condition of the streams has been brought about, though much remains to be done, "more especially by the sanitary authorities." *One suburb, Moss Side, practically a part of* Manchester, remains outside and independent of the city and its dealing with its sewage is not satisfactory. There is a sewage farm that is often complained of, which is not remarkable seeing that its area is equal only to about one acre per 1000 of the population, but even Moss Side promises *to do better.*

Diphtheria at Darwen.

The recent report of Dr. S. W. Wheaton of the Local Government Board on a serious epidemic of diphtheria at Darwen is a severe indictment of the sanitary condition of the town and by implication of the town council. The general unwholesome conditions prevailing in the town are considered responsible for the extensive prevalence of sore-throat, which after its introduction facilitates the spread of diphtheria. Dr. Wheaton recommends increased isolation accommodation, thorough overhauling, and where there is insufficient fall relaying of the sewers. The town council are also recommended to endeavour to replace the pail-closets by water-closets or slop-water-closets.

Suicide in Salford.

Is suicide becoming more common? One would say yes if the state of things which was disclosed the other day at the *Salford Borough Sessions were typical of the whole country.* Mr. J. M. Yates, K.C., congratulated the grand jury on the light calendar. Although there were only 11 cases for trial no fewer than six were charges of attempted suicide. In two only was any cause assigned but in these it seems to have been poverty. In one case a girl, aged 15 years, had for some *time assisted her mother* who is a *dressmaker*, but work was scarce and she was told to try to get work elsewhere. Having failed to find any she tried to drown herself. She pleaded guilty and was sentenced to one day's imprisonment. The next case was that of a woman, 54 years of age, who was deserted by her husband *some months ago*, and had found great difficulty in providing herself with food and lodgings, so she tried to drown herself. "Her own and her sister's recognisances in 40*s*. were taken." A joiner, 52 years of age, had a day's imprisonment for attempting to drown himself. The cause was not stated. A woman, whose age was not given, for a similar offence was bound over to come up for judgment "if called upon." A girl, aged 18 years, was sentenced to one day's imprisonment, but in this case neither the manner nor the reason for the attempted suicide is given. The severest punishment was inflicted on a man, aged 63 years, who had tried to cut his throat. He gave himself several severe gashes with a razor which but for prompt medical aid would have proved fatal. He was sentenced to 14 days' imprisonment "in the second division." It seems difficult to discover the principle regulating the punishment for attempts at self-murder. One can understand the feeling of depression produced by unsuccessful efforts to get work, the vision of the future rendered all the more hopeless from the physical exhaustion brought on by want of food. In many cases, however, especially in young girls, mere petulance and momentary ill-temper seem to be the only assignable causes for suicide; in others, of course, disappointed *love*, or what passes for it, is held to be a sufficient excuse for the throwing away of life. Has our system of education any influence, and if any what influence has it *on the ideas prevalent* as to the sacredness of human life? It almost seems as if ill-disciplined, ill-regulated minds were in the ascendant.

May 20th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox at Swansea.

THERE have been 55 cases of small-pox in Swansea since the beginning of *the epidemic* in December last and until recently there has been experienced no difficulty in [illegible] patients in the small-pox hospital. On May 12th

[illegible] Library
[illegible] Medical College

however, the medical officer of health (Mr. Ebenezer Davies) applied to the borough justices for an order to remove two children who had contracted the disease and who were residing in one house where there were four other persons. The entire household was said to be unvaccinated. The order was made but has not been complied with and the children's father, who is a stallholder in the public market, is to appear before the magistrates on May 22nd on a charge of obstruction. Since the order was made the mother of the children and a maid-servant have been attacked with the disease. The latter has been removed to the hospital.

The Royal Alexandra Children's Hospital, Rhyl.

Rhyl has always been a popular resort for the inhabitants of the great industrial centres of the Midland counties and of Lancashire, so that it is not at all surprising to find that the majority of patients treated in the Royal Alexandra Children's Hospital come from these counties. In 1901 they numbered 474 of the 710 patients taken into the wards. Of this total 58 were medical, 69 were surgical, and the remainder were convalescent cases. The institution was first established upon a very small scale in the year 1872, but 20 years later the demands upon its resources were so great that in 1894 it was decided to erect an entirely new building and Messrs. Alfred Waterhouse and Son prepared designs including a convalescent home to accommodate 100 patients, a central administrative block for a staff of 25 nurses and a hospital for 60 patients. The foundation stone was laid by Queen Alexandra in 1894 and the central block was formally opened by the Prince and Princess of Wales on May 12th. The hospital has been in use since 1900 and the convalescent wing is to be erected when sufficient funds are forthcoming. The hospital, which has an uninterrupted sea frontage of 266 feet, contains four wards on two floors to accommodate 15 beds in each and on two sides of each ward are balconies on to which beds can be wheeled. There are also recreation rooms, single bed wards, an accident ward and an operating theatre. The walls of the wards are lined with a glazed brick dado, above which is adamant cement and all corners are rounded and ledges avoided. The sanitary offices are at the angles of the wards with cross ventilating passages. The whole building is lighted with electric light and the passenger lift is worked by electric power. In the administrative block are sea-water baths, and a Finsen lamp and Roentgen ray apparatus have been installed. In the beautiful little chapel there is a window given by his widow in memory of the late Mr. Murray Browne, formerly Local Government Board Inspector for North Wales and who for some years was honorary treasurer and secretary to the hospital.

Death under Chloroform.

A man, 42 years of age, died at the Swansea General Hospital on May 16th while under chloroform. He was about to be operated upon for ununited fracture of the arm but the operation had not been commenced at the time of his death.

Payment for Patients treated at the Pasteur Institute in Paris.

Several persons who had been bitten by rabid dogs in Pembrokeshire have been sent for treatment to the Pasteur Institute in Paris and so far with the best results. The expenditure involved was borne provisionally by the county council and it has now been sanctioned by the Local Government Board which requires that the county council shall formally approve the expenditure after receiving medical reports of the cases particularly concerned.

Public Slaughter-house for Bristol.

The Bristol Health Committee, after having had the question under consideration for some time, has at length passed a resolution recommending that a scheme shall be brought up providing for the erection of a public slaughter-house. There are altogether in the city about 120 private slaughter-houses, but a large proportion are quite unsuitable for the purpose to which they are put.

The Medical Officer of Health of Barton Regis, Bristol.

Upon many occasions THE LANCET has insisted upon the undesirability of medical officers of health visiting cases of infectious disease notified to them and the Local Government Board has frequently expressed the same opinion in communications addressed to sanitary authorities. The Barton Regis Rural District Council having passed a resolution calling upon its medical officer of health, Dr. Edward Crossman, to make a detailed report upon every infectious case notified to him received a letter from the Board in the terms above indicated, and upon Dr. Crossman declining to fulfil the requirements of the district council, which were in direct opposition to the instructions of the Board, he has been called upon by the council to send in his resignation. It will be interesting to see whether Dr. Crossman will receive the ultimate support of the Board, though there is no doubt that he has the sympathy of his colleagues in his endeavour to uphold the traditions of his profession.

Children's Convalescent Home at Weston-super-Mare.

The convalescent home at Weston-super-Mare in connexion with the Bristol Royal Hospital for Sick Women and Children is apparently conducted upon economical lines, for during the past year 322 patients were treated in the institution at a total cost of £480, although there are only 28 beds in the home. Patients are sent to the home, not only from the Bristol hospitals, but from the public elementary schools and by the Bristol Board of Guardians.

Vaccination Expenditure.

At the meeting of the Okehampton (Devon) Board of Guardians held on May 10th it was reported that the vaccination fees for the past quarter amounted to £75, whereas under the old regulations the annual cost for vaccination was £35. Several of the guardians considered that it was very hard on the ratepayers that several prominent residents of Okehampton should be revaccinated at the expense of the rates, but it was pointed out to them that all persons were entitled to free public vaccination. The finance committee reported that one of the public vaccinators had been revaccinated by his assistant and had charged 2*s.* 6*d.* for the operation. The committee, however, was of opinion that as the assistant was not engaged by the guardians the auditor of the Local Government Board would surcharge that amount.

The Winsley Sanatorium.

At the meeting of the Bristol City Council held on May 13th it was decided to contribute a sum of £1000 towards the cost of the Winsley Sanatorium and to give an annual donation of £260 towards the maintenance of the institution, conditionally that four beds be reserved exclusively for Bristol cases.

May 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

General Council of the University of Edinburgh.

THE statutory half-yearly meeting of this body was held on May 7th. The only matter of medical interest was a report on the medical curriculum, in which it was pointed out that the fifth year had been added to the curriculum with a view to give the student in the end of his course more time for the clinical subjects. This expectation, the report holds, has failed entirely. At the same time the report somewhat illogically says that difficulties have arisen in connexion with the hours for systematic lectures because an additional hour, namely from 11 to 12, is wholly taken up with hospital teaching. The fact is that this extra hour of clinical instruction has been a great gain to the student and it is in virtue of the additional year that he has been able to take full advantage of it. The question of the rearrangement of class hours is dealt with and a workable time-table is added to the report. The report further suggests that the academic year should be divided into three terms of 10 or 11 weeks each and that the winter session should begin for all classes on Oct. 1st. It is also proposed that examinations shall be held three times during the year, and, save under strict regulations, no student who has failed to pass an examination shall be allowed to attend the succeeding classes of the course. The order in which students are to take out their classes ought to be prescribed. The meeting agreed to this report and ordered it to be sent to the University Court. The proposals are eminently practical and many of the professors and teachers have long held that alterations ought to be made in the directions indicated. It is to be regretted that the Court seems to be so unwilling to carry through any considerable modification of the existing order of things. It probably dislikes general council agitation, but it would be wise to carry out recommendations of this kind, for they embody the experience and the mature opinion of a large body of teachers. The question is one deeply affecting the interests of the student and there is no selfish interest involved or rival interest of extra- and intra-mural school.

Examination of Clinical Morbid Products in Edinburgh.

The latest phase of the relations between the Royal College of Physicians of Edinburgh and the Edinburgh Town Council is the circulation of a letter to medical practitioners in Edinburgh in which it is intimated that in consequence of the decision of the town council to transfer to the *Usher Institute* of Public Health the reporting on morbid products received by the medical officer of health from practitioners in the city the College has resolved to cease to issue reports on such products received through the medical officer of health after May 15th. As, however, it is the wish of the College to place the resources of its laboratory freely at the service of the medical profession, in the interest of the citizens, the College has instructed the superintendent of the laboratory to receive morbid products directly from practitioners in the city and to report thereon without fee. It is hardly necessary to say that there is a difference of opinion regarding this action and as to its exact significance.

The Proposed Psychiatric Clinic at the Edinburgh Royal Infirmary

This matter is still under the anxious consideration of the board of managers, which body has applied to the members of the staff for their opinion. As I intimated some weeks ago there is still considerable diversity of opinion regarding the scheme. Of course the alienists are running a big scheme for all its worth and with an interesting and curious optimism as to the depth of the public pocket. Meanwhile the stern fact faces the managers that their annual ordinary expenditure exceeds their ordinary revenue by something like £16,000 and that for the last quarter alone it exceeds it by £10,000. Many shrewd people hold that there is a limit to public giving for any one charity, no matter how deserving it be. This view is based partly upon what happened during the time that war funds were being raised, for it was then found that many persons merely transferred their giving from one charity to another Another factor which is to be also borne in mind is that the need of providing suitable establishments for patients suffering from tuberculous disease of the lungs is deeply impressing the public mind and will tend to divert money in that new direction.

Aberdeen University

At a meeting of the University Court on May 13th a letter from Professor Trail was read intimating gifts by himself of two sums of £100 each, to be named the Dickie Fund and the Nicol Fund, the income of which is to be used yearly for giving prizes to students in botany and zoology, "to encourage students to acquire skill to fit them for research, to promote a fuller knowledge of the flora and fauna of Scotland, to induce students to aid in the equipment of the university for teaching and research in these sciences, and in the work of societies and institutions (especially in Aberdeen and in the north of Scotland) organised to promote a fuller recognition of the interest and value of the biological sciences in education and otherwise; to connect these objects with the names of his teachers (Professors Dickie and Nicol) in botany and zoology, and to express in a slight measure his sense of what he owed to their instruction and example."

May 20th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal City of Dublin Hospital

THE "Gigas" bazaar in aid of the Royal City of Dublin Hospital was, as its name implied, an immense undertaking. After running several days it was brought to a conclusion on May 19th and notwithstanding the very unfavourable weather which prevailed it seems to have proved a financial success On its last day it was visited by several of the captains and officers of the German squadron, including those of the flagship *Kaiser Wilhelm II* The foreign visitors were received by the medical staff of the hospital and the members of the committee.

The Coronation Celebration in Dublin

A large and influential meeting of the citizens of Dublin was held in the Antient Concert-room on May 10th in furtherance of the movement for celebrating the coronation in Dublin. Sir Christopher J Nixon, President of the Royal College of Physicians of Ireland, addressed the meeting and in the course of an interesting speech suggested that the occasion might be celebrated by the establishment of some permanent monument of charity, such as an addition to the present deficient accommodation for sufferers from consumption in Dublin. Mr Thomas Myles, President of the Royal College of Surgeons in Ireland, expressed himself in favour of the establishment of a fund for the widows and orphans of the fallen Dublin Fusiliers.

Surgeon-Captain T J. Crean, V.C

The annual dinner of the Royal College of Surgeons in Ireland took place on May 10th at the College buildings in Stephen's Green and was preceded by a very interesting ceremony Immediately before the banquet the President of the College, Mr Myles, in the presence of the Lord Lieutenant and a distinguished company, presented the diploma of the honorary Fellowship to Surgeon Captain Crean, V.C, recently decorated by his Sovereign for personal gallantry in the field. On Dec. 18th, 1901, at Tigerskloof, he attended the wounded in the fighting line, was twice wounded, and only desisted when it was thought that the second wound was likely to prove fatal. Surgeon Captain Crean, of the 1st Imperial Light Horse, is the fourth of those holding the diploma of the Royal College of Surgeons in Ireland who has received the much-coveted honour of the Victoria Cross. After the dinner His Excellency warmly congratulated the new honorary Fellow of the College.

Royal Medical Benevolent Fund.

At the annual meeting of the Belfast branch of this fund held on May 15th it was reported that the state of the funds was satisfactory, although 52 members of the profession in Belfast did not subscribe. Professor W Whitla was elected President, Dr H. L. McKisack secretary, and Dr R. Purdon treasurer

The Royal University of Ireland

At a meeting of the Senate of the Royal University of Ireland held in Dublin on May 15th a report was received from the Medical Committee (at which it appears there were only three members present) recommending the names of certain candidates as "extern" examiners and, notwithstanding the recent senatorial election, three out of the four suggested were medical men living in Dublin. The Senate declined to take action on such a report and wisely decided to refer the whole matter back for further consideration. Not only was the meeting of the Medical Committee at which these recommendations were made a small one, but two out of the three members present were Dublin senators. Further, a motion, of which notice had been given by the President of Queen's College, Cork (Sir Rowland Blennerhassett, D L.), was passed directing the attention of the Standing Committee to the inadequate representation of the various Queen's Colleges on the examination boards of the Royal University. There will never be any confidence in this question of examiners until the only examiners from Dublin in the university are those connected with University College, Stephen's Green, which is affiliated with the Royal University, and the other provincial schools in Cork, Belfast, and Galway must be fully represented. To appoint "extern" examiners from Dublin would only accentuate the present agitation. Dublin men should surely be content with examinations in Trinity College, the two Royal Colleges (Surgeons and Physicians), and the Apothecaries' Hall; but the provincial medical men who teach in the medical schools of Cork, Galway, and Belfast must be represented on the university with which their colleges are so closely connected. "Extern" examiners can be appointed, if required, from England and Scotland, and in this way the practice of other universities will be followed.

Londonderry District Lunatic Asylum

At the meeting of the committee of management held on May 15th it was reported that during last year 581 patients had been under treatment, the daily average being 488, as compared with 475 for the previous year At present in the asylums in Derry and Gransha and in the Derry and Limavady workhouses there are 491 patients, against 469 at the same date last year

Queen's College, Belfast

The chair of Physiology at Queen's College, Belfast, is now vacant owing to the resignation of Professor W. H. Thompson on his appointment as professor of the Institutes of Medicine in the School of Physic of Trinity College, Dublin, and the chair of Natural History which has been filled by Dr.

R. O. Cunningham since 1870 will be vacant at the end of the present summer session owing to his resignation, a source of deep regret to his colleagues and the large number of students whom he taught.

May 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Cocaine Anæsthesia.

AT the Society of Surgery on May 7th M. Chaput read an interesting communication on the indications for local cocainisation, spinal cocainisation, and general anæsthesia respectively. In his opinion local cocainisation in combination with inhalation of ethyl chloride is the best method of producing anæsthesia for small operations; it is indicated whenever possible in the case of diabetics and patients to whom the idea of general anæsthesia is alarming. It may be used in superficial laparotomy and in operations for hernia. It is contra-indicated in the case of children, excitable persons, and complicated laparotomies. Spinal cocainisation is to be recommended for operations on the lower limbs, the anus, the rectum, and the genito-urinary organs of both sexes. It is applicable to superficial laparotomies and to operations for hernia. It is indicated for operations on the thorax and for difficult laparotomies when general anæsthesia would be dangerous. General anæsthesia is the only method available for children, for excitable persons, and for complicated (supra-pelvic) operations. It is the best method when operations of moderate or considerable extent are to be performed on the supra-pelvic region in individuals whose general condition is satisfactory, but it is contra-indicated in the case of timid patients and those whose general condition is bad.

Administration of Chloroform.

At the meeting of the Academy of Medicine held on May 13th M. Laborde said that in his opinion the system followed in the administration of chloroform ought to be in accordance with the teachings of physiology. The danger at the commencement of the anæsthesia lay in the arrest of the cardio-respiratory reflex consequent on irritation of the termination of the trigeminus; to this cause was due the primary syncope which was so serious. The danger might, however, be averted by the preliminary injection of a solution of morphia or, still better, a solution of narceine. It was, for instance, a good plan to inject a cubic centimetre of a solution consisting of hydrochlorate of morphia, 10 centigrammes; sulphate of atropine, one centigramme; sulphate of sparteine, one gramme; and distilled water, 10 grammes. The morphia might be advantageously replaced by narceine which was very soluble but the dose of which must be doubled or tripled, making 20 or 30 centigrammes for the above prescription. It was also useful to paint the nasal and pharyngeal mucous membrane with cocaine. Finally, the employment of the forceps for making rhythmic traction of the tongue averted all the dangers of syncope. The forceps might even be placed in position when the administration of the chloroform was commenced, for on the least alarm a few tractions sufficed to restore respiration and circulation. M. Laborde did not attach much importance to the use of mixtures of definite strength; he thought that what he had already recommended was in most cases a sufficient safeguard in the giving of chloroform.

The Public Health Laws and Epidemics of Typhoid Fever in Country Districts.

At the same meeting of the Academy of Medicine M. Fiessinger pointed out some defects in the public health laws which, he said, could never be made effective since the mayors were placed in a position subordinate to the prefects. A prefect is an official personage and may lose his appointment if he does his duty. The intention of the public health laws was good, but a mayor who was an influential politician could render the greater part of them inoperative. In support of this view M. Fiessinger gave some details of an epidemic of typhoid fever which had been raging for eight years in a small country town. Up to the present time there had been more than 800 cases and about 80 deaths. The infection arose from the spring which supplies the town becoming polluted by infiltrations from a distance. The spring issues from the base of a hill and is fed by an underground stream which comes from a high tableland and sinks into the earth near some houses where typhoid fever is prevalent. M. Chantemesse said that he was able to confirm these statements but that the relations existing between the public health service and the authorities gave rise to difficulties which had hitherto proved insurmountable.

May 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Rights and Privileges of the Medical Chambers.

AT the recent meeting of the Medical Chamber of Berlin and the Province of Brandenburg the proceedings took an unexpected turn owing to some remarks made by the representative of the Government. Readers will remember[1] that the Lichterfelde Hospital is boycotted by the medical profession of the district in which it is situated, for the local practitioners will not send patients to be under the care of Professor Schweninger, the chief medical officer of this hospital. One of the incidents arising out of this was that at a recent meeting of the District Council of Teltow to which the hospital belongs the district president (Landrath) Herr von Stubenrauch, said that in boycotting the hospital the medical men were influenced solely by personal animosity to the chief medical officer and that they were acting against the interests of the patients. These utterances of an influential Government official were naturally resented and at the last meeting of the medical chamber Dr. Heyl of Schöneberg proposed a motion to the effect that the chamber regretted that Herr von Stubenrauch had made erroneous statements with regard to the medical profession, but when the matter came on for discussion Herr von Bethmann, the president of the province of Brandenburg, who was acting as the representative of the Government in the medical chamber, rose and said that the chamber was not entitled to pass a resolution of that kind. The medical chambers, he said, were bodies holding official positions subject to the authority of the State and were possessed of jurisdiction only over the medical men of the district, but by passing a resolution of that kind the chamber would have the appearance of assuming jurisdiction over the Landrath, which would be contrary to the law. If the chamber believed that it had a grievance against the Landrath the proper course for it to adopt would be to make a complaint to the president of the province—i.e., the speaker himself—the Landrath being one of his subordinates. The members present at the meeting were much astonished on hearing these statements, and after a long discussion the chamber resolved to express its thanks to Dr. Heyl and to pass to the order of the day. These proceedings have been much commented on both in the daily and in the medical press, and it is admitted that the medical chambers have completely disappointed the hopes even of those medical men who were most desirous that there should be an official representation of the profession. Some even say that if the chambers are not entitled to resist attacks on the profession it would be better to have no chambers at all, but rather to have the free associations as before, for the latter were not hampered by the Government interfering with their discussions and the interests of the profession were looked after by them better than they are by the medical chambers.

Cancer Statistics.

A collective investigation on the spread of cancer in Germany was made by a committee under the presidency of Professor von Leyden in October, 1900, and the results have now been published in the *Klinische Jahrbuch* under the auspices of the Cultus Ministerium. 25,376 circulars were sent to all the hospitals, asylums, and medical men of Germany and replies were received in answer to the majority of these communications. The published report states that at the period in question 12,153 cases of cancer were under medical care, 4439 being in men and 7714 in women, so that there were 215 cases in each million of the population. The greatest number of cancer patients were reported from Thuringia and the fewest from East Prussia. As regards the age of the patients the report states that four men and 15 women were between 15 and 30 years of age, 47 men and 151 women were between 30 and 40 years, 25 men and 587 women were between 40 and 50 years, 664 men and 865 women were between 50 and 60 insisted, against his medical attendant's advice, in making a passage to another port. It should only have been about a 12 hours' run, but when about half way to the destination it came on to blow a gale—as it *can* in the Mediterranean at very short notice—and the little yacht pitched and rolled to such an extent that the unhappy writer was with difficulty kept in his berth. In such weather he had always been sea-sick, but now he fully realised the danger in every movement and strain of a clot being detached and the results thereof. He knew fear as he hopes never to know it again—helpless paralysing fear with every lurch of the yacht; *he was not sick.*

---

[1] THE LANCET, March 8th, 1902, p. 706.

I suppose a belt of any sort is presumed to be beneficial on the theory that sea-sickness is caused by movement or displacement of the viscera, but whatever relief belts may give I don't think that their action on visceral movement has much to do with it. During what we all soon hope to call the late war I saw soldiers accustomed to violent gymnastic exercises, and rough riders whose viscera get a lot of shaking up, quite as sea-sick as anyone else; and a proprietor of a circus in South Africa who takes his company all over the world informed me that his acrobats suffered quite as much at sea as ordinary humanity.

Space will not permit my opening up the wide subject of treatment, but I must say a word about boats. Every man whose business or pleasure takes him continuously backwards and forwards across oceans and seas knows exactly what boats of the lines he travels by have the reputation of being good and comfortable sea-boats; that is, boats that have an easy motion *over* rather than *through* a heavy sea, thereby lessening the shock of impact so trying to the sea-sick—boats also which do not unduly roll with that terrible interval at the extreme angle which sailors express by saying "she feels as if she was never comin' back again." Details as to the behaviour of boats at sea are not to be obtained from the clerk in the company's office from whom the passenger books his berth, and the size of a boat is not by any means a guarantee of her comfort in a sea-way. As to yachts, in their behaviour at sea they vary enormously and therefore in their capabilities of producing sea-sickness. All get their reputation, but if even doubtful they are always described to the would-be purchaser as "the finest sea-boat of her tonnage afloat," and often such a high-sounding title as *Queen of the Ocean* (I hope I am not treading on anyone's toes—I have not Lloyd's latest list) is given when she might be more appropriately christened the *Emetic.*

I am, Sirs, yours faithfully,
Parkstone, Dorset. HENRY GOODALE.

A QUESTION UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT.

To the Editors of THE LANCET

SIRS,—I received the inclosed letter from the medical officer of health of my district. I should be glad to know: 1. If a medical man must not notify according to *his* (*own*) *opinion.* 2. The fact of no bacillus being found—does this make the case certain, as the swab might be taken too late? 3. Can the district council refuse payment if the notification s sent in good faith?—I am, Sirs, yours faithfully,

Upper Pontnewydd, March 27th, 1902. A. W. HAYLES.

[INCLOSURE.]

Cwmbran, R S O., Monmouthshire, March 25th, 1902.

DEAR SIR,—I received a notification signed by your assistant, Dr. Wilson, on March 13th, of a case of diphtheria at Woodside-road, the child's name being Davies. I sent a swab taken from the child's throat to the Jenner Institute of Preventive Medicine for examination and the report says that there was no diphtheria bacillus found. The Llantarnam District Council direct me to write to you to say that under the circumstances you will not be entitled to charge the notification fee of 2*s.* 6*d*

Yours truly,
W. E. C. MURPHY,
Medical Officer of Health.

⁂ 1. The medical practitioner must act upon the basis of his own judgment.[1] There is no other standard of action contemplated or recognised by the Notification Act. Moreover, the medical officer of health has to bear in mind that the general practitioner's opinion is the only thing which enables a bacteriological examination to be made. 2. The fact that no diphtheria bacillus was found on one occasion does not, in our view, justify the extreme step which was taken in this case. The swab may have been imperfectly applied or there may have been other factors militating against a correct result. 3. We are not prepared to give a general reply to this query, but we are strongly of opinion that, assuming there to be no question of bad faith, no sanitary authority which properly comprehends its responsibilities should discourage notification in this fashion. It seems to us that the medical officer of health would have been well advised had he invited the coöperation of the notifying practitioner in securing another specimen for bacteriological examination. If the opinion of a medical practitioner is ruthlessly reduced to *nil* as the result of one negative bacteriological examination local sanitary administration will be at a rather low ebb.—ED. L.

CHLOROFORM ANÆSTHESIA DURING SLEEP.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 29th, p. 911, you describe an article on Chloroform Anæsthesia during Sleep by Dr. N. Stone Scott of Cleveland, Ohio, in which is discussed the question as to whether such a thing is possible without the patient being awakened. I have on two occasions successfully administered chloroform to patients who were asleep, in one case to a youth aged 16 years, and in the other to a child. In the former case the patient was suffering from paraphimosis. Chloroform was administered slowly at the commencement. No struggling was experienced and circumcision was performed. This took place about 3 P.M. and the patient did not wake until next morning when he was greatly surprised to find that the operation was over. In the case of the child the administration of chloroform was equally succ Complete anæsthesia was rapidly produced and an was performed.

I have had no failures and my experience these two cases, but "the admitted rarity of rence" is my reason for bringing them to notic

I am, Sirs, yours faithfully
Wolverhampton, April 1st, 1902. W.

PROFESSIONAL LONGEV

To the Editors of THE LANCET.

SIRS,—*Apropos* of the quotation from THE LANCET of March 22nd (p. 856), I think it your readers to know that Mr. Nathaniel Davidso I was apprenticed in 1852, will attain the patriar 97 years on Saturday, March 29th. He became a of the Royal College of Surgeons of Edinburgh in Licentiate of the Society of Apothecaries in 1 probably the senior survivor of both institu Davidson, after practising in London for 30 ye a Licentiate of the Royal College of Physicians in is, I am happy to say, in very good health.

I am, Sirs, yours faithfull
CHRISTOPHER
Cavendish-square, W., March 25th, 1902.

THE BATTLE OF THE CLUBS.

To the Editors of THE LANCET.

SIRS,—Ever since I have been in practice—13 y have acted as surgeon to the Victory Lodge of the payment being 4*s.* per member per annum. In I wrote asking that my salary should be increas 6*s* on account of the amount of work to be done owing to the fact that the position of the members warranted my asking for an increase. The secretary on Sept. 17th wrote stating that the lodge could not accede to my request. The same day I gave notice to terminate my appointment on Dec. 17th. Several neighbouring practitioners were nominated as surgeons for the vacancy but not being satisfied with the secretary's statement that I resigned owing to my refusal to attend members at a distance they referred to me, and on hearing that the years, 912 men and 1009 women were between 60 and 70 years, and 815 men and 935 women were over 70 years of age. 70 per cent. of the male patients and 68 per cent. of the female patients suffered from cancer of the digestive organs, 31 per cent. of the women suffered from cancer of the genital organs, 25 per cent. of the women suffered from cancer of the breast, and 15 per cent. of the men and 16 per cent. of the women suffered from cancerous disease of the skin.

[1] The words of the certificate are, "I hereby certify and declare that, in my opinion," &c.

Venereal Diseases in Prussia.

A collective investigation of the prevalence of venereal diseases in Prussia was held in 1900 and, as already mentioned in these columns[1] the medical profession of the country was provided with blank forms on which they were requested to state the number of venereal patients treated during the month of April, classifying them according as they suffered from syphilis, soft sore, or gonorrhœa. The papers were collected by the Government Medical Department of the Cultus Ministerium, the well-known statistician, Professor Guttstadt, acting as recorder. Answers were received from 63·5 per cent. of the medical men and the returns supplied showed that there were 40,920 venereal patients, of whom 75 per cent. were men and 25 per cent. were women. To arrive at the real number of venereal cases in Prussia Dr. Blaschko rightly observes in the *Medical Reform* that 36·5 per cent. must be added to the above figures, that being the proportion of medical men who had not supplied returns. Moreover, he remarks that there may be a large number of unreported cases attended by unqualified practitioners. Dr. Blaschko accordingly estimates the total annual cases to be about 773,000, a number which he arrives at by multiplying the monthly number by 12. On this computation one out of every 22 adults must contract some form of venereal disease every year. As to the different varieties of venereal disease the report states that 54 per cent. of the cases were gonorrhœa, 6 per cent. were soft sore, and 40 per cent. were syphilis, 27·6 per cent. being fresh attacks. Cases were more frequent in the towns than in the country. Dr. Blaschko has also computed the proportion of venereal patients among the adult male population of the larger towns. The highest ratio was in Königsberg, where it was 44·4 per 1000; in Wilhelmshafen and Charlottenburg it was 38 per 1000 and in Berlin it was 32·4 per 1000. In 1899 there were 27,195 venereal patients in the hospitals, so that only one out of each 29 cases was admitted to a hospital. Dr. Blaschko states that the number of venereal patients in hospital compared with the aggregate of all the hospital patients has decreased continuously since 1877. In 1877 there were 79 venereal cases among each 6000 hospital patients, but in 1899 there were only 43 per 1600. He therefore concludes that whilst hospital accommodation for general patients has largely increased the number of beds for venereal patients is not sufficiently augmented. Quoting the words of the late Dr Firvinico, "la prophylaxie de la syphilis c'est le traitement," he recommends the establishment of either more wards for venereal patients or of special hospitals for such cases. In the conclusion of his article he mentions that a German Society for the Repression of Venereal Disease is in course of formation.

May 19th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Prevention of Diphtheria.

MR. PINCHING, the Director-General of the Sanitary Department, has lately sent round a circular to the various medical practitioners of Cairo informing them that there now exists at the Hygiene Institute of the Government a gratuitous system for examining swabs from patients' throats believed to be diphtheritic. The necessary test-tubes containing a mounted plug of sterilised cotton-wool are kept by the 18 chief druggists of the town and also at the various sanitary offices of Cairo. Attached to each tube are instructions for its use and the practitioner is invited to give the necessary details about the patient. The Hygiene Institute in return informs the practitioner as quickly as possible of the result of the bacteriological examination. Arrangements similar to this exist in some parts of Germany and the United States but not yet, I believe, in England. The Sanitary Department hopes that by this means it will be able to hear earlier of doubtful cases and it can insure a thorough bacteriological investigation which cannot always be carried out by practitioners in the town working in an ill-equipped laboratory. During the last 12 months there have been over 300 cases of diphtheria in Cairo, mostly in the poorer native quarters where there was a small epidemic between October and December last year. Another up-to-date arrangement works well by which the German sanitary inspector of Cairo offers to inject gratuitously as a preventive measure the children who have been in the house with a case certified as diphtheria. He tells me that he has already injected 300 of these "contacts" and not a single case of diphtheria has occurred among them. In not only diphtheria but in every case of infectious disease the Sanitary Department now gratuitously disinfects the rooms and their contents of any infected private house or hotel.

Measures against Plague.

There have of late been no new cases of plague but energetic work has to be continued in many different places. The small staff of English workers is getting gradually knocked up in consequence of much travelling, some anxiety, and the constant effort to galvanise native assistants into doing conscientious work when not under the immediate eye of the inspector. The Government has therefore sanctioned the appointment of two new English medical men as assistant inspectors. It is unfortunate that both plague and cholera are apt to occur in an epidemic form during the hot summer months and this makes it almost impossible for the chief inspectors to take leave at the very time when it is most required. Several of the staff are now in need of a long-deferred European holiday.

Veterinary Report for 1900.

37 cases of glanders and farcy were reported in Alexandria and Cairo but none occurred amongst the Government animals. Mallein is now used in every outbreak and all animals seized by the police are tested before admission to the infirmaries of the Society for the Prevention of Cruelty to Animals. 19 cases of rabies were found in dogs, besides one in a cat, and 10 human beings suffered from hydrophobia. The cases came from five provinces, besides those in Cairo and Alexandria. Both rabies in animals and hydrophobia in human beings have increased during the last three years and much more energetic measures must be taken if hydrophobia is to be stamped out. It is a disgrace to the English occupation that outcast pariah dogs should still be running about in the streets of Cairo and other big towns. They serve no useful purpose and they are a distinct danger to the community. The police periodically poison some scores of them, but every one of them should be energetically destroyed. In the provinces this will take many years to accomplish, but there is no reason why it should not at once be done in Cairo and Alexandria. Outside some of the country villages children are sometimes bitten by rabid wolves. Two years ago, in fact, a boy died from hydrophobia in one of the suburbs of Cairo after being bitten by a rabid wolf who actually attacked him while working in his master's kitchen. The number of cases treated at the anti-rabies institute in Cairo has risen from 88 persons in 1899 to 140 in 1900 and over 180 in 1901. About 200 cases of sheep-pox were reported in Egypt during the year, besides 68 outbreaks of the foot and mouth disease, while 55 cases of anthrax occurred in Alexandria amongst Syrian animals. In the Cairo slaughter-house tubercle was detected in 3 per cent. of the camels, 5 per cent. of the cows, 3 per cent. of the bullocks, and 2 per cent. of the buffaloes, while in Alexandria the disease was found in 8 per cent. of the milch buffaloes, 3 per cent. of the Egyptian cattle, and 1 per cent. in imported cattle. The owners of Cairo dairies are quite willing to have their animals tested with tuberculin and in three dairies the tests all proved negative, but in two others 8 per cent. and 10 per cent. of the cows gave a positive reaction. One of the Cairo dairies has just been unfortunate enough to have a case of typhoid fever among the European staff, but the patient was at once removed from the dairy to a hospital and the strictest sanitary investigation has acquitted the dairy premises and water supply of all blame. Public slaughter-houses have now been provided in 31 towns and the annual number of animals killed has gradually gone up from 387,000 in 1893 to 498,000 in 1900.

Vaccine Institute.

This institute has now overcome all its early difficulties and produced during the year lymph sufficient for 578,000 vaccinations, over 200,000 of these having been called for in the month of April. The yield of vaccine from buffalo calves is found to vary from 15,000 to 25,000 vaccinations per calf, after being mixed with two parts of glycerine and two parts of distilled water. This mixture, adopted on the recommendation of the London Institute, has been found to answer better in Egypt than the lanoline mixture used in India.

[1] THE LANCET April 28th, 1900, p. 1251.

Cairo, May 11th.

Medical News.

CONJOINT BOARD OF EXAMINERS IN PUBLIC HEALTH OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the recent meetings of this Board held in Glasgow the following medical practitioners, having passed the necessary examinations, were admitted Diplomates in Public Health :—

Peter Aitken, Bo'ness; Gilbert Edward Brooke, London; Walter F. Brown, Sheffield; Duncan Fletcher, Harris; James Livingston Loudon, Hamilton; Neil Macvicar, Peebles; William Russell, Paisley, Alexander Watt, Falkirk; and Frank Mayes Willcox, Edinburgh.

UNIVERSITY OF CAMBRIDGE.—Grants from the Balfour Fund have been made to Mr. C. Crossland and Mr. J. S. Budgett to enable them to pursue zoological researches in Africa. Mr. A. Sedgwick, F.R.S., has been appointed a manager of the fund. Mr. A. E. Shipley has been appointed a representative of the University on the council of the Marine Biological Association. The Special Board for Medicine has added the University of Adelaide to the list of recognised colonial schools of Medicine. The new Professor of Arabic is Mr. Edward Granville Browne, M.A., M.B. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Fellow of Pembroke College and late University Lecturer in Persian. He was a student of St. Bartholomew's Hospital. He has published numerous works on Persian travel, religion, and life. The Thurston Triennial Prize of about £54 will be awarded this year at Caius College for the best original investigations published by a member of the College during the last three years on physiology, pathology, or practical medicine. Particulars may be obtained on application to the Master.

CORONATION BALL AND FÊTE AT THE CRYSTAL PALACE.—On July 2nd, at the Crystal Palace, a Coronation ball will be held in aid of King Edward's Hospital Fund. The ball is under the patronage of His Majesty. 2000 square feet of parquet flooring will be laid in the central transept and four large drawing-rooms will be furnished in the south transept. On either side of the drawing-rooms the gardener will construct an English and an Italian garden, the latter with statues and a fountain. Tickets at one guinea each will include special trains from Victoria, supper, ball, and variety entertainment.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—A meeting of the members of the Darwen Medical Society was held on April 1st for the purpose of presenting to Mr. Edgar Alfred Field, M.R.C.S. Eng., L.R.C.P. Lond., one of the members, an illuminated address signed by all the members, together with a midwifery bag fitted with the necessary instruments, on the occasion of his leaving Darwen. Dr. J. T. Ballantyne, deputy mayor of Darwen, in making the presentation, said that the members took that opportunity to express their appreciation of Mr. Field as a fellow practitioner and the high esteem in which he was held by all of them and trusted that every success would fall to him in his new sphere of labour.—On March 25th the members of the Ladies' Class of the St. John Ambulance Association at Coventry presented Mr. Milner M. Moore, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., with a suit case as a mark of their appreciation of his services as honorary instructor.—Mr. J. G. Glasgow, M.R.C.S. Eng., L.R.C.P. Lond., senior assistant medical officer of the Milton Asylum, Portsmouth, has been presented by the members of the Portsmouth Association Cricket Club, of which club he is captain, with an embossed cigarette case. Mr. Glasgow is resigning his appointment at the asylum.—At Padstow (Cornwall), on May 1st, the members of the ladies' branch of the St. John Ambulance Association presented Mr. R. Palk Griffin, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., with a standard lamp, suitably inscribed, in appreciation of his services as honorary lecturer.—Mr. Bartholomew Gidley Derry, L.R.C.P. Lond., M.R.C.S. Eng., has been presented with a carved oak smoking companion by members of the Bodmin Fire Brigade, in appreciation of his services as honorary lecturer to the ambulance class.

AN UNQUALIFIED DENTIST.—At the Cardiff Police-court on May 16th a man who described himself as a chemist and a "merciful tooth extractor" was fined by the stipendiary magistrate £20 for using a description implying that he was a person specially qualified to practise dentistry. The prosecution was initiated by the South Wales and Monmouthshire Dental Association.

LITERARY INTELLIGENCE.—Mr. F. D. How, author of "The Life of Archbishop Plunket," "The Life of Bishop Walsham How," and other well-known books, has written, and Messrs. Isbister and Co., Limited, 15, Tavistock-street, London, W.C., are just publishing, a memoir of the late Mr. William Smyth, L.R.C.S. Irel., whose noble self-sacrifice, even to the laying down of his life, in the cause of duty whilst fighting an outbreak of typhus fever on the poverty-stricken island of Arranmore so thrilled the hearts of men when it was made public in the autumn of last year.

THE ROYAL INSTITUTION.—The Nebular Theory formed the subject of the Friday evening discourse delivered by Sir Robert Ball at the Royal Institution on May 16th. He said that the laws governing systems of bodies in motion made it infinitely probable that nebulæ had a tendency to become flattened towards a plane in which their constituent parts described approximately circular paths, all in one direction but with a greater velocity at the centre than at the circumference. Spiral nebulæ were discovered by Lord Rosse. Photography had shown that they were vastly more numerous than was formerly supposed and it was now believed that there were thousands of them which could be photographed though they were invisible in any telescope. Only a few nebulæ were so placed that their spirals were seen from the earth in front view or plan; the well-known one in Andromeda was the best example and a splendid photograph of it was thrown on the screen, as well as many other photographs of nebulæ, most of which had been taken at the Yerkes and Lick observatories in America. Actual motion of a nebula had not been observed until towards the end of 1901, when successive photographs of the new star which appeared in Perseus in February of that year showed that a nebula in that region of the heavens was moving with wonderful velocity.

LONDON HOSPITAL.—The new operating department of the London Hospital has just been completed (with the exception of the eastern end which is in course of erection) and was opened by the Lord Mayor on May 22nd. It is situated on the third floor of the old front block of the hospital on the site formed by demolishing the old attics, together with the previously existing operating and clinical theatres. The new department consists of a theatre, four operating-rooms, and three anæsthetising-rooms, all facing north, with large windows and top lights. In addition there are four recovery-rooms or small wards, five operation wards, instrument- and sterilising-rooms, and nine or ten rooms for the use of the surgeons, nurses, and others. The operating theatre has a marble gallery for students fitted with teak sides and gun-metal rails. The floors of the theatre, the operating-rooms, the anæsthetising-rooms, and the central corridors are in marble mosaic and the walls and ceilings are lined with opalite. All angles are rounded. The doors are polished oak with swing hinges. Hot water is supplied from an apparatus in the basement and is all boiled. Each day's cold water supply has been previously boiled. In the sterilising room there is a Manlove and Alliott's steam disinfector for dressings, coats, &c. The air to supply the theatre, operating-rooms, and anæsthetising rooms is led from the garden by means of a glazed tunnel and is driven by an electric fan through a canvas water screen and cotton-wool filters, after which it is warmed by steam coils. The vitiated air is drawn out of the rooms by electric fans in the gables of the roofs. The total length of the new buildings, as shown on a plan, is 270 feet, and the average width is about 60 feet. The whole of the department is lighted by electricity. The buildings and fittings have been executed in accordance with the designs and under the superintendence of Mr. Rowland Plumbe, F.R.I.B.A., the architect to the hospital. The funds have been provided by the generosity of a donor who stipulated that the department should be open to all denominations and that his name should be kept secret.

DEATH OF A CENTENARIAN.—The death occurred at Devizes on May 12th of Richard Giddings who attained the hundredth anniversary of his birthday in August last.

CROWNHILL CONVALESCENT HOME.—The annual meeting of the subscribers of the Crownhill Convalescent Home, near Plymouth, was held on April 16th. The medical report stated that 278 patients had been admitted during 1901, an increase of 38 compared with the previous year. The financial statement showed that the receipts amounted to £454 and there remained an unfavourable balance of £30. Dr. O. A. Hingston announced that the late Mrs. Fowler of Plympton had bequeathed him £1000 to be used as he thought best for the home and he proposed to admit about 30 additional cases every year.

PREVENTION OF TUBERCULOSIS —An influentially-attended meeting was held at Dorchester on May 6th to consider the proposal that Dorset should join with Devon and Cornwall in the establishment near South Brent, Devon, of a sanatorium for the treatment of consumption. The Earl of Ilchester presided, supported by Lord Portman, Lord Stalbridge, the Earl of Shaftesbury, Sir Henry Peto, and Dr. W. Lush. Considerable opposition was shown to the scheme largely on the ground that the sanatorium is not in Dorset. Eventually the report of the committee, which was in favour of joining with Devon and Cornwall, was referred to it for further consideration. The chairman stated that attention will now be given to the question of providing a sanatorium in Dorset.

DONATIONS AND BEQUESTS.—By the will of Mr. Henry Tate £2000 are bequeathed to the Hahnemann Hospital and Homœopathic Dispensary, and £1000 each to the Liverpool Royal Infirmary, the Liverpool Northern Hospital, and the Woolton Convalescent Institution, and £500 to the Liverpool Ladies' Charity and Lying-in Hospital.—Under the will of Mrs. Eleanor Thorp of Cheltenham £1000 are bequeathed to the Leeds General Infirmary, £4000 to the Cheltenham General Hospital, and £2000 to the rector of Cheltenham upon trust for the sick and needy parishioners of St. Mary and St. Matthew.—The late Mrs. Nathaniel Montefiore has bequeathed £2000 to University College Hospital and £200 to the Chelsea Hospital for Children.—£2000 have been left to the Croydon General Hospital under the will of Miss J. Keen of Croydon.—Sir Reginald Beauchamp has presented £1000 to the Board of Management of the Norfolk and Norwich Hospital for the purpose of endowing a bed in memory of his parents.—By the will of Lord Rookwood, under certain conditions £1200 are bequeathed to the trustees of the cottage hospital at Hatfield Broad Oak for the general purposes of the hospital.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The twenty-sixth annual meeting of this association was held at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, London, W., on May 20th. There was a reception with refreshments and opportunity for the inspection of microscopic specimens, lantern-slides, photographs, and diagrams lent by the President, Mr. W. McAdam Eccles, Mr. Pernet, and Dr. Kelynack. Professor G. Sims Woodhead took the chair at the meeting which followed. The annual report was read by the honorary secretary, Dr. J. J. Ridge, in which it was stated that there were at present 520 members and 438 student associates. Meetings of medical students had been held at the London, Guy's, and St. Thomas's hospitals and the *Medical Temperance Review* had been widely circulated. An international medical manifesto condemning the use of alcoholic beverages on physiological grounds had been prepared in conjunction with the American Medical Temperance Association and the Association of German-speaking Abstaining Physicians. This was being extensively signed at home and abroad. The funds of the association were low and there would have been a deficit but for an opportune legacy of £250. An interesting and valuable address was then given by Mr. Eccles on Cirrhosis of the Liver and its Causation by Alcohol and Otherwise, illustrated by lantern views. A discussion ensued in which Dr. R. Paramore, Mr. A. B. Olsen, Dr. T. Morton, Dr. Heywood Smith, Mr. T. Rushbrooke, and Dr Ridge took part, and a vote of thanks was unanimously accorded to the reader of the paper.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Hospital Contributions by Local Authorities.

A BILL has been introduced in the House of Commons by Mr. Walter Long, President of the Local Government Board, to empower county councils and other local authorities to make contributions to hospitals.

HOUSE OF COMMONS.

WEDNESDAY, MAY 14TH.

Hospital Provision at Lucknow.

Mr. WEIR asked the Secretary of State for India, in view of the fact that the hospital for the native troops at Lucknow was unprovided with a ward or room of any kind for serious ophthalmic or other cases of a special character, whether he would take such steps as might be necessary to ensure the provision of suitable accommodation for such cases.—Lord GEORGE HAMILTON replied: I have no special information as to the details of the accommodation provided at this hospital, but I am confident that the matter may safely be left to the discretion of the Government of India, who, aided by their professional advisers, are always anxious to make the best arrangements that are practicable for the treatment of soldiers who are on the sick list or in hospital.

Death Certification in Scotland.

Mr. WEIR asked the Lord Advocate if he would state the number of interments which took place in each of the six crofting counties last year without the production of a medical certificate of death.—The LORD ADVOCATE replied: On April 26th, 1901, in reply to a similar question, I pointed out to the honourable Member that a medical certificate of death is not a necessary condition of burial in any part of Scotland. There is no information in the Registrar's office as to the number of interments without the production of a medical certificate.

THURSDAY, MAY 15TH.

Sanitary Condition of the House of Commons.

This subject was raised again on the vote in Committee of Supply for the Houses of Parliament Buildings. Members complained of the conditions of the atmosphere when the House was sitting, of uncomfortable draughts, and of inefficient ventilation, and one gentleman suggested that the air introduced into the chamber should be drawn, not from the level of the river, but if it were possible from the summit of the clock tower. Complaint was also made of the unsatisfactory kitchen accommodation.—Mr. AKERS-DOUGLAS, First Commissioner of Works, undertook to inquire into the various points raised and gave the assurance that the Ventilation Committee is making satisfactory progress with its work.

Enteric Fever at St. Helena.

Mr. LAURENCE HARDY asked the Secretary of State for War whether he was aware that the garrison of St. Helena was suffering from an epidemic of enteric fever which had been caused by a failure of the water-supply and by deficiency in the supply of milk and other necessaries; whether he could give the statistics as to the cases of enteric fever amongst the British troops in the island; and whether he would take immediate steps to secure that a good water-supply and milk and other necessaries should be provided.—Mr. BRODRICK replied: There were 98 cases of enteric fever among the garrison at St. Helena on May 9th. No report has reached me of failure of the water-supply or deficiency in the milk-supply or other necessaries. Supplies of tinned milk and medical comforts have always been available there and every possible precaution is being taken.

Parochial Medical Officers in the Crofting Counties.

Mr. WEIR asked the Lord Advocate if the Secretary for Scotland would grant a return showing the names of the parishes in each of the six crofting counties in which the parochial medical officer had been dismissed by the parish council within the last seven years; the return to distinguish cases where a cause for dismissal was assigned from cases where no such cause was assigned.—The LORD ADVOCATE replied that the Secretary for Scotland would be prepared to grant the proposed return.

Medical Examination of Travellers at Calcutta.

Mr. WEIR asked the Secretary of State for India, in view of the fact that the shed in which passengers leaving Calcutta by outward bound steamers assemble for medical examination had been out of repair for several months prior to Jan. 8th last, and that passengers had to await the arrival of the medical officer for examination in the open street, whether he would ascertain if the shed had been put in repair yet? and whether he would consider the expediency of taking such steps as might be necessary to require the punctual attendance of the medical officer, especially in connexion with the morning sailings?—Lord GEORGE HAMILTON replied: I have no knowledge of the allegations made by the honourable Member. I will bring them to the notice of the proper authority in India.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

MYXŒDEMA: A QUESTION OF TREATMENT.

To the Editors of THE LANCET.

SIRS,—Will you or any of your readers kindly give me information upon the following case?

A woman who had been suffering for some time from myxœdema was put on thyroid gland treatment with the result that all the myxœdemal symptoms vanished. But she developed a most distressing urticaria. During last year the thyroid treatment appeared to lose its effect as the old symptoms returned, but the rash completely disappeared. As the patient was becoming rapidly worse I tried a different preparation of thyroid gland. This was followed by very marked improvement in the myxœdemal symptoms, but the rash has returned worse than ever. We have tried numerous local applications and many drugs internally without the slightest improvement. Apparently the rash appears immediately the patient is under the influence of the thyroid gland.

I am, Sirs, yours faithfully,

MYXŒDEMA.

May 14th, 1902.

THE R.A.M.C. UNIFORM.

To the Editors of THE LANCET.

SIRS,—Referring to "Surgeon-Captain's" letter in THE LANCET of May 10th, p. 1370, I should be glad to know where he gets his order from respecting the wearing of "Sam Browne" belts by volunteer medical officers.

I am, Sirs, yours faithfully,

SURGEON-LIEUTENANT-COLONEL.

May 13th, 1902.

"FILTHY ADVERTISEMENTS."

To the Editors of THE LANCET.

SIRS,—I bespeak your kind hospitality for space to notice the letter of your Canadian correspondent "G. D. B." in THE LANCET of May 3rd, 1902, p. 1294. I am the last man in the world to carp at fair, sharp criticism, but the use of the phrase "some filthy beast" indicates anything but a judicious mind and one totally unfit to pass judgment on opinions or principles held by an opponent. In my study of political economy I found the cause of much human misery demonstrated and, with Mill, Professor Fawcett, aye, Mrs Fawcett, I was convinced that early and improvident marriages were a prolific source of poverty, misery, and crime. My daily experience yielded overwhelming evidence of this and I determined to give my views publicity. I knew them to be true, though unpopular, and up to now I have not seen such views successfully answered by logic or reason. The present war has yielded overwhelming proof of my contention in the tremendous percentage of rejections of army recruits in London, Sheffield, and elsewhere. The main object of my treatise is to evoke thought and secure a due appreciation of the responsibilities of marriage and parentage. Is this in any sense a filthy object? I reply, a thousand times no, but it is laudable and seasonable. Capable thinkers have times and again declared this evil and the reckless unions of mere children need prevention by law infinitely more than newspapers require a curtailment of their liberty. But perhaps "G. B. D." is wroth and furious because I mention a check in my treatise. But, Sirs, there are checks and checks, and the one I give is by a qualified physician. It is perfectly moral, prudent, and healthful, and can in no way lead to wrong actions. Like you, Sirs, I abhor the very word abortion and brand it as wickedness. But checks are not immoral *per se*. At every turn we use them. Where would be the ennobling science of medicine without checks? The charlatan and the mountebank would fatten at the expense of the skilled M.D. But we very properly check them. All I attempt is to check an imprudence among the sexes which, when left to run riot, produces evils so prolific, intense, and lasting as to threaten the vitality and progress of the nation. Herewith I send copy of my little work and am, Sirs, yours faithfully,

Nottingham, May 19th, 1902. W. J. DOUSE.

THE SOPORIFIC EFFECT OF ONIONS.

To the Editors of THE LANCET.

SIRS,—A gentleman informed me the other day that Pilsener lager beer always had a very drowsy effect upon him which he attributed to the "leeks" used *in its manufacture. (The onion-like flavour of this* beer, I have understood, was due to the resin used in the casks.) He, however, was positive that it was due to leeks and further said that his brother, a medical man, had told him that the onion tribe contained opium. That onions have a soporific quality is well known but to what is this due? Is it to any compound of the "allyl" series?

I am, Sirs, yours faithfully,

May 5th, 1902. INQUIRER.

*** The notion that lager beer contains onions, garlic, or leeks is absurd and erroneous. The faint garlic-like flavour is natural to lager beer and is due to the fact that it is brewed at a low temperature. The soothing effect of an onion poultice is well known, but this cannot be referred to opium. The soporific effect of German beer is greater than that of small English beer probably because the Germans employ more hops.—ED. L.

FEES FOR INSURANCE EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—I have the pleasure of handing you herewith copy of a letter received from a medical man employed by one of the provincial managers of my office in reply to the receipt of our usual report form upon which a notice is printed that a 10*s*. 6*d*. fee is payable when the sum assured is below £250. The tone of the communication speaks for itself but I do not wish to infer that in this respect it is representative.

I may call to your notice that already two or three of the leading life offices are now assuring lives for moderate amounts without medical examination, as this ordeal is objected to by the public, and in small business the fee is a heavy initial charge on the premium. Policies for small sums assured form a very large percentage of the total number issued. Under these circumstances a hostile attitude on the part of the medical profession to the receipt of a 10*s*. 6*d*. fee is much to be regretted, as in the course of a few years it will induce the best assurance offices to meet the convenience of the public by abandoning the medical examination altogether and by safeguarding themselves by other means. I inclose my card.

I am, Sirs, yours faithfully,

May 9th, 1902. ACTUARY.

[COPY.]

May 6th, 1902.

DEAR SIR,—Herewith find Mr. ———'s Policy (*sic*) duly filled; I protest against your fee, there is no reason for it whatever; yr Co. suffers by it, as where you cheeseparc, Medical men will be quits with you by giving bad lives, and it is most illogical as well, our skill, trouble, knowledge, &c., can't vary because the sum insured is £250—or £249 19*s*. 11¾*d*.; but you can get men to do it even less; why don't you take tenders for such cases? you cd get them done for 2*s*. 6*d*. per head. *I now demand* MY FEE of £1 1*s*. Yours truly,

———, M.B.

*** We do not know what time and labour have been required of M.B. in return for 10*s*. 6*d*. by the provincial manager in question, but, as a rule, the labour asked of the medical man is out of all proportion large in regard to the fee. We do not think that the best assurance offices will long remain the best assurance offices if they dispense with medical examination of the applicant for insurance.—ED. L.

THE "Y" FUND.

SURGEON GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Sir George Duffey, Professor A. Ogston, Mr. W. Garton, Dr. L. Hepenstal Ormsby, Dr. G. T. Beatson (Glasgow), Mr. James Taylor (Chester), Major C. R. Johnston, I M.S., Captain and Mrs. C. E. Grey Stalkartt, Miss Furness, Mrs. Stocker, Dr. and Mrs. J. Dallas Pratt, "A Well-wisher," "A Sympathiser"; Civil Surgeons (attached to the Royal Army Medical Corps) H. Croly, E. Lynch, and G. P. Meldon, Surgeon-General G. J. H. Evatt, A.M.S., Lieutenant-Colonels W. R. G. Hinds, A.M.S. (retired), J. McGann, A.M.S. (retired), C. White, A.M.S. (retired), J. W. Belcher, A.M.S. (retired), J. G. Williamson, A.M.S. (retired), and W. H. Steele, A.M.S. (retired); Deputy Surgeon-General Kilkelly; and the following officers of the Royal Army Medical Corps: Lieutenant-Colonels R. D. Hodson, H. Grier, N. Alcock, A. Anderson, A. W. P. Inman, H. G. Hathaway, J. Latchford, G. Coutts, G. H. Le Mottée, Surgeon-Major E. J. Hunter, Major D. M. Saunders, Captains L. Way, C. H. Hopkins, and J. Davies, and Lieutenants S. Adye-Curran and F. Boner. The fund now amounts to £175. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens-terrace, Hyde Park, London, W.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

THE following additional subscriptions to this fund have been received:—

	£	*s.*	*d.*
Colonel R. Exham, C.M.G.	1	0	0
Major R. J. Faylo, D.S.O.	1	0	0
Captain J. Stuart Gallie	0	10	6
Major H. E. Cree	0	5	0

	£	*s.*	*d.*
Major G. Scott	0	5	0
Previously acknowledged in THE LANCET	86	9	6
Total	89	10	0

WANTED—A HOME.

A MEDICAL man writes: "A friend who has retired upon an income of £140 per annum has two insane daughters, the insanity being of a mild type. His own house is small and he would like to have the children treated away from home. He cannot pay more than 8*s*. or 10*s*. per week for each, but he would like to do this and not to send them to a public asylum. Can any reader of THE LANCET give me information privately?"

TO MEDICAL FREEMASONS—A LETTER OF THANKS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your columns have the pleasure on behalf of my husband and myself of thanking all those medical Freemasons who so kindly and generously came forward to assist in my husband's successful election on Friday last to the Royal Medical Benevolent Institution? Most sincerely do we thank all.

I am, Sirs, yours faithfully,

Bildeston, May 21st, 1902. CLARA SOMERS IVENS.

MEDICAL EVIDENCE IN CORONERS' COURTS.

A COPY of the *Liverpool Echo* of Monday, May 5th, has been sent to us containing an account of an inquest held by the county coroner, Mr. S. Brighouse, at Bootle, on the body of a woman who had died at the Bootle Hospital from the effects of burns. Dr. Dunne, the house surgeon of the hospital, was present at the inquest, but the so-called medical evidence as to the cause of death was given by a nurse who had been summoned by the coroner in preference to the resident medical man. This course the house surgeon protested against, whereby he drew upon himself the rebuke of the coroner. We are entirely on the house surgeon's side. Medical evidence, to be worth anything in a court of law, whether it be a high court or a coroner's court or a county court, must be given by a qualified medical man.

◆

Quandary.—The situation is one that often arises and in country districts a man must decide for himself how he will act. Our general advice is that he should in no circumstances associate himself with an unqualified practitioner as anæsthetist.

B.A. Oxon. (*Bradford*) is thanked for the newspaper cutting. The gentleman's communications to the press are copious and his prejudices are well displayed in all of them.

A.B.C.—The address of the Incorporated Society of Trained Masseuses is 12, Buckingham-street, Strand, W.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Evening Post (Jersey), Lancaster Examiner (U.S.A.), Le Courrier d'Aix les-Bains, Wandsworth and Battersea District Times, Lancashire Daily Post, Dorset County Chronicle, Ipswich Times, Yorks Observer, Aberdeen Journal, Aberdeen Free Press (Weekly), Surrey Advertiser, Times of India, Plymouth News, Irish Times, Glasgow Herald, Southport Guardian, East London Observer, St. James's Gazette, Lancashire Post, Suffolk Chronicle, Newcastle Chronicle, Echo, Yorkshire Post, Star, Western Morning News, &c.*

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

SATURDAY (31st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), *University College* (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (26th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Annual Conversazione. Reception by the President. 8.45 P.M. Oration:—Dr. S. Mackenzie: The Powers of Natural Resistance or the Personal Factor in Diseases of Microbic Origin. Exhibition of Drawings of London. Music. Smoking.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Communications:—Mr. J. S. Sewill: A Case of Fractured Tooth.—Mr K. W. Goadby: Sterilisation of Impression Composition. Paper:—Mr. J. H. Targett: Some Growths about the Jaws.

TUESDAY (27th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. T. J. Tonkin: Some General and Etiological Details concerning Leprosy in the Sudan.—Mr. J. Hutchinson: Leprosy in Natal and Cape Colony.

FRIDAY (30th).—EPIDEMIOLOGICAL SOCIETY (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Meeting.

SATURDAY (31st).—OTOLOGICAL SOCIETY OF THE UNITED KINGDOM (Anatomical Department of the *Medical School of Trinity College, Dublin*).—11 A.M. Cases, Specimens, and Demonstrations by Dr. Macnaughton Jones, Prof Cunningham, Prof. Coffey, Prof. Birmingham, Dr Dempsey, Prof. U. Pritchard, Mr. A. H. Cheatle, and Dr J. Horne.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (26th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Clinique. *(Skin.)*

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Rickets, its Manifestations and Treatment.

TUESDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. R. L. Bowles: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Cole: Mania.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Sir W. Gowers: On Some Spinal Mysteries.

WEDNESDAY (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

THURSDAY (29th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Medical Anatomy and Physical Diagnosis.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration of Surgical Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Kellock: Hare Lip and its Treatment.

FRIDAY (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. Clarke. Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Reece: Small pox and Vaccination.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with *by them!* Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not to* THE LANCET Offices.

Subscribers, *by sending their subscriptions direct to* THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Messrs. Arnold and Sons, Lond.; Mr. W. Alabaster, Lond.

B.—Dr. J. L. Bogle, Bordighera; T. B. Browne, Ltd., Lond; British Laryngological, Rhinological, and Otological Association, Lond., Hon. Secretary of; Mr. H. Butterfield, Northampton; Dr. James Barr, Liverpool; Messrs. Brown, Gould, and Co., Lond.; Mr. John R. de C. Boscawen, Truro; Messrs. Bates, Hendy, and Co., Lond.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

THE POWERS OF NATURAL RESISTANCE OR THE PERSONAL FACTOR IN DISEASE OF MICROBIC ORIGIN.

Being the Annual Oration of the Medical Society of London, delivered on May 26th, 1902,

BY STEPHEN MACKENZIE, M.D. ABERD., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—There can be few amongst us who do not rejoice in the privilege we have of living in an epoch of such progress and mental activity as the present. The great increase of knowledge of the latter half of the last century is found in every branch of science, but it impresses us, perhaps, most in the advance of scientific knowledge in our own profession. It has been brought about by improved means of exact and minute research aided by instruments of increased precision. So that if medicine, in its widest sense, cannot be claimed as an exact science, our methods of dealing with the complex and difficult problems of disease in the living and ever-changing body are as exact as the present state of science permits. Great as have been our advances we cannot doubt that they will be infinitely greater and probably more rapid in the future Many, however, are dazzled and led away by the apparent completeness of our recently acquired and almost daily increasing knowledge and are inclined to overlook, to neglect, and almost to deride the knowledge which we have acquired by the patient industry and accumulated experience of our predecessors—the work that our fathers have given the best years of their life to accomplish. Our President (Dr. W. H. Allchin) touched upon this point in his address last year. There could be no greater or more inexcusable mistake. Whilst gratefully acknowledging and utilising the newest methods and knowledge as aids to medicine and surgery, theoretical and practical, we must consider them in relation to the observed facts, empirical and scientific, that have been acquired since medicine has been studied as an art or a science. Some of the aphorisms of Hippocrates, the clinical observations of Sydenham, and the pathological observations of John Hunter, are as pregnant of truth and as worthy of being treasured in the memory now as when they were first promulgated, and are in no sense less important than are the most recent discoveries in the laboratories of the bacteriologist and the chemist. It is quite certain that the accurate record of careful observations of the phenomena of disease will always be valuable additions to medical knowledge, whether or not capable of explanation or use at the time they were made. We see striking illustrations of this in the writings of the three great Guy's physicians—Bright, Addison, and Hodgkin. There have been many stages in arriving at the knowledge which we at present possess. The progress of morbid anatomy and the revelations of the bacteriologist and chemist have given great precision to our knowledge and have opened out new methods of research and treatment. The task which I have set myself on the present occasion is to point out that whilst availing ourselves of all scientific discoveries we must not overlook or forget the valuable knowledge which we already possess and may still further acquire by careful, patient, and persevering clinical work. The tendency of the medical mind at the present time seems to be to attach too great importance to the germ or seed and too little to that of the body or soil in diseases of microbic origin. I propose to pass under review a few diseases of this class and to endeavour to point out the share or relative importance of these two factors in such diseases.

INFLUENZA.

Let us first take the case of influenza. It presents the extreme end of a series of infectious diseases—i.e., diseases of microbic origin. It prevails pandemically at irregular and often long intervals, usually followed by epidemics for some years. When pandemic it is remarkable for the number of persons who are attacked and the rapidity with which it spreads from country to country. Neither race nor class, sex nor age, afford exemption. It is so widely spread when pandemic that very few escape, though probably a very few are immune, and these attribute their escape to some nostrum or the disinfectant most in fashion. At these times the seed is everywhere and almost everywhere it finds a congenial soil, so that the natural resistance or personal factor, as far as susceptibility goes, is practically *nil*. Not so the effect; though said to be the smallest bacillus known, like the Biblical grain of mustard-seed it gives rise to very great results. In the aged, in those suffering from pulmonary and cardiac disease, and in those devitalised from any cause, it is a very serious malady often leading to a fatal issue. Though in the robust it is often apparently a comparatively trivial disease this generation has learned that it is to be treated with great respect and that apparently slight cases neglected may lead to very grave results. We have learnt, too, that it may be attended with very serious and dangerous complications, such as abscess of the brain, purulent otitis, phlebitis, affections of the heart and nervous system, &c. Whether these complications are the direct effect of Pfeiffer's bacillus or are due to a mixed infection has not been fully worked out.

The subject of mixed infections raises a very interesting question of great importance in several of the infectious diseases, indicating that the seed is not always pure or that the tissues the resistance of which has been broken down by one microbe fall a ready prey to others, but into this point I do not propose to enter

Lastly, we have learnt that the effects of an attack may be of prolonged duration, continuing even for years. Whether they depend on tissue changes effected by the direct action of the bacillus or its toxins in the attack or the latter surviving long after the attack of influenza is uncertain, but we see in diphtheria the supervention of paralysis some weeks after the acute stage has passed off, and in syphilis the occurrence of nervous lesions years after all other active manifestations which we recognise as directly syphilitic have ceased to present themselves. Let us turn now to another subject—tuberculosis.

TUBERCULOSIS.

When I began the study of medicine we were still in the throes of battle as to what was tubercle and what tubercle was. The unitarian doctrine of Laennec did not by any means meet with universal assent. The microscope was pressed into service to decide what was the essential constitution of tubercle and diligent search was made for the "tubercle cell" as there had been for the "cancer cell," as fruitless in the one case as in the other. Then followed the epoch in which Villemin showed that tubercle was inoculable, though many pitfalls were encountered in establishing this fact. Finally, in 1882, Koch was able to demonstrate that the specific cause of tuberculosis in all its various forms was a micro-organism, the bacillus tuberculosis, that it was present in every tuberculous lesion, and that without this there was not any tuberculosis. The gropings to establish its nature, often highly scientific, sometimes blind, were at an end; the efforts of many of the keenest and ablest workers to understand its morbid anatomy and pathology were harmonised and their errors were corrected and we obtained an absolute criterion to which we could appeal to decide what was tuberculous. It was left to the clinician and sanitarian to apply this knowledge in the treatment and prevention of disease. With the aid of the bacteriologist we have learned a great deal of the life of the tubercle bacillus both inside and outside the body and of the ways by which tuberculous persons become affected. But in this respect the tendency has been perhaps to concentrate attention on the microbe and to devote less consideration than its importance demands to the human host in which it finds a lodgment. This is seen not so much in the deadhouse where the gross changes in the organs are forced on our notice as in the wider aspects of the subject which deal with the causation and prevention of tuberculosis. We are apt to think too much of the *seed* and too little of the *soil*. We have learned since Koch's discovery of the bacillus that from many sufferers from tuberculosis, more especially in pulmonary phthisis, the secretions or discharges given forth contain the bacillus in an active condition and that the clothes and handkerchiefs and the beds and the floors and walls of the dwellings of the sick are contaminated in this manner so as to be a source of danger to others. These secretions and discharges undergo desiccation and are commingled with other particles constituting dust which are inhaled with the air we respire, and haply finding in the respiratory or digestive organs conditions favourable for their growth increase and multiply and bring about tuberculosis. We have reasons for believing that casual bacilli may not only reach the respiratory and digestive organs but may make their way by the blood-vessels into practically all parts of the body where, in favouring conditions, they set up tuberculous processes. Thus are accounted for cases of tuberculous meningitis, tubercle of the kidney, &c. We have learned that the bacillus tuberculosis may be contained in the milk, the butter, the cheese, and the flesh which we consume as food. In recent years great efforts have been made to exclude this mode of infection by the extermination of tuberculosis in cattle and the destruction of food-stuffs derived from infected bovines. Like a bolt from the blue came the recent pronouncement of Koch himself at the late British Congress on Tuberculosis that the risk of transference of tuberculosis from cattle to human beings was so slight as to be a negligible quantity. The gauntlet thus thrown down was immediately taken up. A Royal Commission has been appointed to consider and to report on the subject. Already evidence has been tendered that such transference does take place, a fact not disputed by Koch himself. Many must admit that the evidence not only as to the fact but also of the frequency with which tuberculosis is derived from bovines is in need of revision and consideration. Dieudonné, Cattle, Shennan, Still, Carr, and Colman have shown that in the tuberculosis of infants the primary seat of infection in most cases is through the respiratory and not the digestive tract, and further Koch in his address to the Congress said: "It is just as likely that these cases of intestinal tuberculosis were caused by the widely propagated bacilli of human tuberculosis." Cattle writes: "It is not only milk that goes into the mouths of children; they grub about on all-fours, plastering their fingers with the tuberculous dust hidden away in inaccessible corners and then put their fingers in their mouths." It is more than possible that the danger of infection from food has been over-estimated. It is none the less our duty to use all the measures which experience dictates to prevent the entrance of the bacilli by this route, and we should be guilty of folly if we relaxed the measures of prevention now in use until we have a decisive verdict on this point.

But it is of the *soil* in which the tuberculous seed grows that we have also to take account. We have learned that the bacillus tuberculosis is so widely disseminated that no one is exempt from the risk of infection. The dust inhaled in many dwellings, in public rooms, in vehicles, and in the streets is often contaminated with the bacillus. Strauss has shown that in cotton-wool plugs in the nostrils of those in attendance at the Charité Hospital, Paris, tubercle bacilli were found in nearly a third of the cases examined and that they proved infective to animals. Dieudonné found tubercle bacilli and pyogenic cocci on the hands and in the noses of children from the age of nine months to two and a half years whose fathers or mothers were the subjects of tuberculosis. Though the protective arrangements at the entrance to the respiratory passages to some extent safeguards the entrance of the bacilli, this protection is by no means complete, and when adenoids or some malformation of the nostrils compel oral breathing it is very imperfect. This is shown by the great frequency of pulmonary tuberculosis. Post-mortem experiences reveal to us that tuberculous changes are found in the lungs and other parts of persons dying from various non-tuberculous diseases or killed by accident—placed by different writers at from 30 to 90 per cent.—but which have become arrested and obsolete. So that not only are all liable to become infected, but we know that in a much larger number of persons than was formerly imagined actual infection does take place. But we learn from this fact also that the infection may be but slight and temporary, and that within the body and in the tissues there exist physiological mechanisms that arrest the invasion and bring it to a standstill. We know also that where the risk of infection must be considerable, as in the aggregations of consumptives in hospitals, very few who move and live among them contract the disease. Though the experience of all hospitals has not been so favourable as has that of the Royal Hospital for Consumption at Brompton it has been stated that over a considerable number of years the incidence of phthisis amongst the physicians, nurses, and servants of that institution has not been greater than that of the general population.

Thus it is demonstrated that the human soil is not in all persons a favourable one for the growth of the tuberculous seed, and that the human organism has a considerable power of resistance and self-protection, very happily illustrated by Osler by the "Parable of the Sower." Dr. W. Howship Dickinson has within the last month published an able and interesting sermon with St. Matthew's Parable of the Sower for his text. Dr. Dickinson has treated the subject of tuberculosis on almost exactly the same lines as myself but in his own peculiarly felicitous manner and literary style. It is equally obvious from the great frequency of tuberculous diseases that all are not equally fortunate in this respect—i.e., in the powers of natural resistance; or, in other words, some are more vulnerable than others. Mankind is naturally resistant to tuberculosis (Kanthack). On what this vulnerability immediately depends we need not here discuss, but we know a great deal of the circumstances in which tuberculosis occurs. We know that it may occur at any age, that its various forms have special age proclivities, and that the majority of deaths from tuberculous affections, as a whole, occur between 20 and 30 years of age. We know by the writings of our predecessors and by our own experience that many inherit and some acquire a tendency to tuberculosis. There can be no doubt that the progeny of the tuberculous are much more liable to tuberculosis than are those in whose family no such strain runs. On what that predisposition depends opinions may differ and we have no absolute knowledge. Whilst congenital tuberculosis, whether placental or germinative, is an established fact, it is extremely rare, but most who are born of tuberculous parents and become tuberculous are not, we believe, actually so at birth. Inheritance in bovine tuberculosis is believed to be answerable for more than one-half of its very considerable mortality. We are often able to detect the tendency by their conformation and we know that they often show a marked tendency to catarrh. I do not discuss the nature and significance of what used to be called the strumous or scrofulous diathesis. We are also quite aware that pulmonary and other forms of tuberculosis do occur in those of robust physique with well-formed chests, but this does not detract from the importance of our experience that the delicate and the frail or those of feeble vitality are the most prone to become tuberculous. The great liability to catarrh in the delicate offspring of tuberculous parents by causing inflammation of the air-passages doubtless weakens their powers of resistance to the tuberculous bacillus which is nearly always at hand. Alcohol again is a predisponent. How often do we hear in taking the history of a family, otherwise clean as regards tuberculosis, the statement that a relative died from consumption but that "he gave way to drink"—an explanation that in the minds of his family this was the cause of his becoming tuberculous? It has been shown that those who are intemperate or who have opportunities of drinking show a higher mortality from phthisis than do others and that the children of the intemperate are more prone to become tuberculous than are those of the temperate. No doubt through alcohol persons acquire or inherit a lessened power of resistance to tuberculosis. Diseases like measles and whooping-cough, which are often complicated with broncho-pneumonia, and diabetes, which greatly reduces the powers of vital resistance, may open the door to tuberculosis.

In the exactness of our recently-acquired knowledge of the pathology there has been a tendency, as I have already stated, to deal lightly with the accumulated experience of the past and to set little esteem upon the laborious work of the great masters of medicine. A timely protest against this tendency has been recently made by Sir Dyce Duckworth in his admirable address on "The Personal Factor in Tuberculosis" which deals with this important subject with an ability and length that I cannot command and which I have read since writing this oration. The personal factor in the clinical aspect and in the pathology of tuberculosis is of quite equal importance to that of the microbe essential as that is for the production of tubercle. "The microbe," writes Professor Vaugeley of Bordeaux, "is nothing whilst the organism in which it thrives is the main factor." How thoroughly this is borne out in the treatment of tuberculous diseases. When once the seed has taken a firm root in the body we cannot with certainty at the present time kill it. It may grow or it may wither, we may cut it out when it is purely local and accessible, in some parts we may destroy it by only question between the lodge and myself was one of salary they withdrew their names, and on Dec. 17th the lodge was still without a surgeon and they were obliged to ask me to continue to act for the time being. In January four more names were put forward and to these I addressed a letter stating all the facts, three of the four withdrew their names. The other wrote me the following letter.—

38, Old-street, E.C., Jan 29th, 1902.

DEAR DR. JONES,—I received your letter yesterday and am sorry that I had not received an intimation earlier, for the Druids approached me a fortnight ago and asked me would I allow myself to be nominated as a candidate. I then inquired what was the reason of your resigning and they informed me you would not visit their prescribed distance. On these grounds I allowed myself to be nominated and I cannot very well now withdraw as I have another of their branches at the usual rate Had I known before what was the difference between you and the club I certainly would not have allowed myself to be nominated

Yours faithfully

I DORRAN

In reply I wrote—

DEAR DR. DORRAN,—I thank you for the letter of the 29th inst in which you state that the Druids secured your consent to be nominated by telling an untruth, yet you say you cannot now withdraw Of course, I can only appeal to you again not to accept less than 6s. per member, *if you do I shall consider your action* as a deliberate attempt to undersell a neighbouring practitioner and I think the profession, to whose judgment I propose to submit the whole correspondence, will be of the same opinion. Yours faithfully,

EVAN JONES

At the end of February this gentleman was appointed at 4s. per annum. The above shows how much chance there is of success to any man who makes an attempt to improve the status of club practice I fear his only satisfaction will be in the fact that he has given up attending men who could well afford to pay more.

I am, Sirs, yours faithfully,

Goswell road, E.C., March 29th, 1902. EVAN JONES.

THE ACETYLENE LIGHT IN OMNIBUSES.

To the Editors of THE LANCET.

THE LANCET of March 1st, p. 608, contained some
to acetylene as being injurious to the health of those
roximity to lamps burning this gas. Knowing
hose engaged in and about the manufacture of
re has never been any complaint of any dele-
from their intimate association with the gas
astonished at the statements made by your
ventured to call the attention of two of the
bers of this association, Professor Vivian
Dr Boverton Redwood, to his remarks and
their reply which I should be obliged if you
insert in your next issue.

I am, Sirs, yours faithfully,

LACEY DOWNES,

Secretary to the Acetylene Association

er-lane, Cheapside, London, E.C., March 18th, 1902.

[ENCLOSURE.]

London, March 15th, 1902.

nes, Esq., Secretary, *pro tem.*,
lene Association, 11, Ironmonger-lane,
Cheapside, E.C.

—In accordance with the request conveyed by your
11th inst. we have given careful consideration to state-
in an article on the Acetylene Light in Omnibuses published
CET on the 1st inst.
r of this article alleges that grave complaints of the smell
have been made by passengers as well as by drivers, and
he apprehension that injury to health may be caused by the
phosphorous compounds present in acetylene made from
al carbide of calcium. The average proportion of impurities
to is extremely small, being in the case of phosphoretted
0·041 per cent. and in that of sulphuretted hydrogen
cent., or in the aggregate less than one-tenth of 1 per cent
ding to our experience a lamp leaking to the extent of 1 per
its "make" of gas produces a smell which is stronger than any
ve observed in the use of acetylene generators, except during
cing and recharging. We therefore consider that the volume of
ing gas cannot exceed this very small proportion, and as this 1 per
itself only contains $\frac{1}{25}$ of 1 per cent of phosphoretted hydrogen
would at once be diluted with an enormous volume of air it is in
opinion impossible for it to "give rise to symptoms of poisoning"
and absurd to suggest that it might produce "phossy jaw."

We are, dear Sir, yours truly,

(Signed) VIVIAN B. LEWES

BOVERTON REDWOOD

*** Cases of sickness due to acetylene gas escaping from omnibus lamps have undoubtedly been reported and in this connexion we may refer to a communication from a correspondent which was published in THE LANCET of March 15th, p. 789. As the above chemists point out, the percentage amount of impurities is exceedingly small, yet these are sufficient to make the gas decidedly offensive. The question as to how far acetylene, pure or impure, is injurious to health is obviously one for the medical profession to decide.—ED. L.

DRUNKENNESS AND THE ABUSE OF NARCOTICS.

To the Editors of THE LANCET.

SIRS,—I cannot allow Dr J. B. Hunter's assertion in THE LANCET of March 29th, p. 919, that "this nation will never be made sober by any other means" than legislation to pass unchallenged. The revenue returns, for last year, showing an actual decrease of a million and a half of pounds sterling instead of a considerable increase as has hitherto been usual, give the impression that temperance may result from other causes than legislation. A large class of this nation, the educated class, has certainly become temperate without legislation. This class, which in a sense may be said to have a public-house always accessible in its dining-room sideboard, has advanced in the last century from habitual excess to moderation and of late in very large measure to almost total abstinence. Yet this change is not due to legislation but to a change in public opinion. Instead of its being considered to be an evidence of "spirit" to drink to intoxication it was thought to be degrading for a gentleman to be drunk, and now it is becoming recognised that it is more healthy to abstain.

Direct legislation by the shutting up of public-houses and by the limitation of the hours of sale can do nothing to change the views of the lower classes, it will rather intensify them by giving the excitement that always arises in evading legislative restrictions. Indirectly, however, legislation can do much by teaching the people to regard drunkenness not as an amiable weakness but as a crime and by punishing not only the criminal but publicans and others who are accessory to the crime.

A temperance reformer has of late appeared that will effect more in ten years than a century of teetotal societies or a thousand legislative enactments—the bicycle. Every growing young man now wants a bicycle, which is bought with money that would be spent on beer, which cannot be ridden to advantage by a man who drinks beer, which affords amusement apart from the public-house and thus occupies time that would otherwise be spent in drinking. *Education*, healthy amusement, and varied interests, by altering the public opinion in regard to drunkenness will result in temperance in the lower classes, even if there were free trade in liquor and anyone might have for the asking a licence to sell it. I am, Sirs, yours faithfully,

April 2nd, 1902. R

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Final Census Returns.—The Plague Epidemic: Alarming Increase.—A Large Improvement Scheme for Calcutta.—A Marwari Hospital for Calcutta.

IT will probably interest your readers of Indian experience to hear the final census returns. The grand total for the whole of India is 294,362,676, of which number 149,953,765 were males and 144,408,911 were females. The provinces show populations as follows. Assam, 6,000,000; Bengal, 74,750,000, Bombay, 18,500,000, Burmah, 10,500,000, Central Provinces, 10,000,000, Madras, 38,000,000; North-west Provinces and Oudh, 47,500,000, Punjab, 20,250,000; and the various States and Agencies, 62,500,000 Of the grand total 29,250,000 form the urban populations, the great mass of the people—over 265,000,000—living in the villages. The excess of males both in the towns and villages is noteworthy This final result of the census has been obtained within one year—a record of work probably unique

Dr. Gloster, Dr Walsh, Dr Horton, Dr. Lewis, and Dr. Justice—plague medical officers who have been given commissions in the Indian Medical Service—have been ordered to proceed home and to join the Army Medical School, Netley, for a course of training.

The weekly plague statement shows a terrible increase in mortality No less than 21,789 deaths are recorded, as against 14,946 in the previous seven days and 6991 for the

Finsen's light treatment or Röentgen rays when it is confined to the skin and superficial mucous membranes; but when deeply seated we at present know of no remedy which will certainly destroy the virus, not even lachnanthes. I say at present because I do not think we ought to be hopeless of effective results from tuberculins or antitoxic serums. It is true that the hopes that were raised by Koch's first tuberculin, prematurely published and boomed by the lay press, did not realise the expectations that were excited. No doubt the pendulum swung *round too completely and the first trials insufficiently* tested or used only in the manner then advised did not offer encouraging results. Nor has general experience, *so* far as it has been employed, been much more encouraging as regards Tuberculin R. Koch has introduced a still newer preparation and there are some who hope that with modifications and in smaller doses distributed over a considerable period, especially in early cases of phthisis, it may yet prove effective. Petruschky claims to have obtained good results by much smaller doses than were originally employed and extending over several courses with intermissions. The method is scientific and is supported by our experience in rabies, tetanus, and diphtheria. Some remedies, such as creasote and guaiacol, of undoubted service in the treatment of phthisis, though not strictly bactericidal in doses that can be safely administered, may possibly diminish the activity of the bacilli and lessen or prevent secondary tuberculosis of the digestive tract by their action on the bacilli in swallowed sputa, but in the opinion of many they only do good by their action on mucous membranes and by lessening cough and expectoration. We disinfect or destroy the sputa and other discharges from the tuberculous, not for the good of the patient, but to prevent the dissemination of the disease to others. Practically our treatment of tuberculous diseases that are not accessible to the surgeon consists in increasing the vigour and resistance of the patient, by life in the open air, *abundance of sunlight which is of great importance as its* chemical rays are strongly bactericidal, thorough ventilation of the apartments of the sick, and by choosing a climate especially suitable for each case when practicable, abundant, very nourishing and oleaginous food, and by strict attention to general and personal hygiene. In *fact, our principal* object and power, whether we recognise it or not, is to endeavour by every means in our hands to raise the natural resistance of the body to the microbe—to devote our attention to rendering the soil an unfavourable one to the growth of the tubercle bacillus. It is encouraging and sometimes astonishing how successful our efforts are in this direction, especially when the circumstances of the patient allow of the full use of the means experience has taught us. It is, however, I think, too great a stretch of the truth to say as has been said that "tuberculosis is one of the most curable of diseases." The wise do not often talk of "curing" tuberculosis. Tuberculosis may become arrested under our treatment, and often without it, but we can never be sure that a quiescent or obsolescent tuberculous process may not resume activity, like Mont Pelée, with eruptive violence under *certain circumstances.* We welcome and admire the princely gifts of Sir Ernest Cassell and other philanthropists for the establishment of sanatoriums for the treatment of the consumptive, and we recognise the duty of municipal and other bodies taking steps for carrying out the "*open*-air treatment" of phthisis so as to extend to the less affluent the benefits which otherwise are confined to the rich or well-to-do. Though the open-air treatment was first practised in England by Dr. Boddington it did not meet with general adoption and this country is at the present time behind others in the means for carrying it out. There is now, however, an awakening to the importance of this method of treatment.

A point, however, to which I most particularly desire to draw attention is that the undoubted and great diminution in the mortality from consumption that has been going on during the last 50 years, not *only in this country, but also in* other countries where statistical evidence is available *preceded* the almost exact knowledge which we have now obtained of the pathology of tuberculosis and the discovery of the bacillus. The great value of the work of the late Sir George Buchanan should always be remembered in connexion with his reports on the conditions under which consumption was most prevalent. This striking diminution in the mortality of consumption has been steadily going on under many unfavourable conditions, before any effective measures were taken for disinfecting or destroying the sputa or separating the sick from the healthy. During the greater part of this time in numerous cases husband and wife, mother and daughter, sister and sister were occupying the same bed when one has been the subject of consumption. It has gone on, too, in spite of the great migration from the country to the towns. There can be no doubt that this lessening of consumption has been due to improved sanitation, to better draining of the land, to improved disposal of sewage, and to the better housing, clothing, and feeding of the general population. Of course, we recognise the great *influence of modern surgery which, dealing with tuberculosis* of the bones and the joints, the glands and the serous cavities, has saved a great number of tuberculous subjects from becoming consumptive. The greatest triumphs in tuberculosis as in other diseases have been in *prevention.*

What lessons do we learn from this general survey of the share taken by the seed and the soil of tuberculosis? First, that we have to prevent or lessen the diffusion of the disease by preventing the dissemination of the tuberculous germs. This is to be done by segregation of the sick either in institutions especially arranged for their care, or when this is impossible by providing that they live in their homes in well-ventilated apartments not occupied by the healthy. We have also to secure the destruction or disinfection of the sputa and other discharges containing the virus and the subsequent disinfection of the rooms that tuberculous subjects have occupied. These measures we are all keenly alive to and we have to continue and to increase our efforts to this end. But we have in addition to taking all means in our power to prevent the propagation and dissemination of the seed not to lose sight of the soil in which it breeds. This is the second direction in which efforts must be made if we are to succeed to lessen still further the prevalence and mortality of tuberculous diseases. What we have to do in this respect is obvious but not easy. We have to increase the natural *powers of resistance to the action of the specific microbe* both in the individual and in the general population. We have to prevent overcrowding and to improve the dwellings of the working-classes and the poor. Poverty is a powerful predisponent to disease of most kinds but especially to tuberculosis. Koch says: "The breeding-places of the tubercle bacillus are in the slums." Sir J. Crichton Browne has said: "Tuberculosis stands in inverse ratio to the rateable value of the property." I remember many years ago before the discovery of the bacillus someone pressing the late Dr. H. G. Sutton to define what tubercle *really* was. He replied: "Tubercle is making shirts at 5*s.* a week." We cannot make the poor rich but it is our duty no less as citizens than as physicians to see that the poor and the working-classes are decently housed and that their dwellings are kept in a proper sanitary state. We must bring the pressure of public opinion *to bear upon municipalities,* urban and rural councils, to improve the conditions under which the poor live. Rich and poor alike must be still further educated as to the imperative necessity of fresh air by means of the "open window" or more scientific methods *of ventilation.* We *must* secure not only for the dwelling but for all places where people congregate—workshops, factories, churches, and theatres—that they do not respire re-breathed and contaminated air. We must use our influence as medical men to prevent consumptives from marrying and propagating offspring predisposed to the disease; we must continue to urge temperance; we must endeavour to rear a population of more robust physique, offering a more resistant soil to the seeds of tuberculosis. What we have to aim at is the improvement of the race. This is a very high, and to some it may seem a transcendental, ideal, *involving great economic and social* problems. But the material prosperity of the country has steadily increased. The poor are better housed, clothed, and fed than they were formerly and we have the encouragement of the past in the last half century teaching that *tuberculous* diseases have materially diminished by the efforts that have been made in these directions.

RHEUMATIC FEVER.

I pass on to the consideration of rheumatic fever. Here our ground is less secure, as the evidence of its bacterial origin is not absolutely admitted at the present *moment,* though it appears to be within almost immediate realisation. Rheumatic fever is a common disease in this country. It has received a great deal of attention at the hands of medical observers and has exercised the minds of most of the thinkers in our profession. The state of our knowledge 30 or 40 years ago may, I think, be fairly summarised by saying that it was believed and taught that rheumatic fever was an acute non-purulent inflammation of many joints and of fibrous tissues, attended by fever and acid sweats, and liable to be complicated by endocarditis and pericarditis; that it was due to an acid in the blood and was to be treated by alkalies. A nervous theory was put forward to explain some of the symptoms but it never took firm root. Prout suggested that lactic acid was the cause of the disease and B. W. Richardson endeavoured to prove this experimentally, but this evidence is not accepted. Latham a few years ago explained how lactic acid might be formed in the body. The acid theory was at one time so firmly established as to appear impregnable. It was, however, but a remnant of the humoral pathology that at one time dominated medicine. The faith of most was shaken when Gull and Sutton published their well-known paper on the Treatment of Rheumatic Fever by Mint-water. They revealed to us almost for the first time the natural history of the disease untreated by drugs and showed that it ran very much the same course and lasted about the same time as when treated by alkalies or other active medicines. This was of course before the introduction of salicin and salicyl compounds into the treatment of rheumatic fever. The kindly banter of Wilks who said that "the use of alkalies in rheumatic fever was to remove the idea of acidity from the mind of the doctor" probably did not a little to help in the same direction. We have since learned by the gradual growth of medical knowledge to take a wider view of the nature of rheumatism. The original conceptions were founded on descriptions of the disease as seen in the adult, but the study of the disease in childhood has enlarged our grasp of its clinical features, and we know that whilst acidity of the urine and the sweat is characteristic of rheumatic fever it occurs also in other acute febrile diseases. But even if an acidity of blood or rather a diminished alkalinity of the blood is true it has still to be ascertained how this is brought about. It is interesting to note that Poynton and Paine found that the organism which they have found in rheumatic fever grows best in an acid medium. We have learned that rheumatism, like tuberculosis, is often an inherited or family disease, that it has many expressions besides the arthritis, and that many conditions such as endo- and pericarditis, some cases of pleurisy, several affections of the skin, tonsillitis, and chorea may occur independently of arthritis and have as much right to be regarded as rheumatic as the joint affection. I am aware that this position is not universally admitted, but though the difficulties of obtaining evidence on this point are great it is those who have devoted most attention to the subject who, as a rule, are most convinced of its truth. But those who hold this view, equally with those who do not see the facts in the same light, have always recognised that there must be another factor besides predisposition to account for the occurrence of rheumatism. What this *tertium quid* is has exercised considerable thought and speculation. The influence of the prevailing pathological doctrine has naturally suggested the possibility of a microbe. This is no new view but was maintained years ago by Hueber, Strümpell, and others. It is admitted or suggested that many or most of the clinical phenomena connected with this disease fit in with the microbic theory and that the morbid anatomy is not opposed to it. Rheumatism is mainly a disease of the first half of life; age exercises a great influence on the form in which it manifests itself. The acute febrile and self-limited course of rheumatic fever corresponds to that observed in other fevers of ascertained microbic origin, whilst the non-febrile or only slightly febrile course of some of the conditions claimed to be rheumatic, such as chorea, is paralleled by diphtheritic paralysis and other nervous affections due to toxins. The occurrence of post scarlet fever rheumatism appears to be an example of "the door being opened" (to use the happy expression of Sir William Broadbent) by the former to the latter, as it is by influenza to typhoid fever. The occurrence of several cases of rheumatism in its various forms in succession in the same house, not confined to members of the same family but in subsequent occupiers, recorded by Mantle and other observers, is strongly in favour of the infective—that is, microbic—nature of rheumatism. Newsholme's valuable work points in the same direction. He has pointed out the epidemic or semi-epidemic prevalence of rheumatism. He found that this is associated with lowness of subsoil water and relatively high temperature of the earth, conditions which either probably influence microbic growth or dissemination. Seasonal influence is considerable, as in typhoid fever and cholera, the greater number of cases of rheumatic fever in London occurring in October and November. Rheumatic fever, like typhoid, confers no immunity to subsequent attacks. On the contrary, a person who has once had rheumatism in any of its forms is extremely likely to have it again, but whether this is due to increased proclivity or simply indicates personal predisposition there is no evidence to show. Several observers, such as Mantle, Achelme, and others, have found micro-organisms in the inflamed joints and blood in rheumatic fever, but their results were not pushed to the point of absolute certainty. Wassermann, Westphal, and Malkoff abroad, and Poynton and Paine in this country, have found a diplococcus which agrees in its general characters. The two latter have obtained this diplococcus in pure culture from human rheumatic lesions and have reproduced by intravenous inoculation in the rabbit endocarditis, pericarditis, carditis, pleurisy, pneumonia, nodules, and a nervous condition resembling chorea, as well as polyarthritis and inflammation of the sheaths of the tendons, and found the same organisms in the induced lesions.

An observation of great interest made by Poynton and Paine is that in a culture from a "sore-throat" in a patient with muscular pains, a history of a previous attack of rheumatic fever, and valvular disease the diplococcus was found. It was isolated and cultivated and was injected intravenously into a rabbit, producing in that animal mitral valvulitis and great dilatation of the heart. This observation and the fact that sore-throat so commonly occurs as an early symptom of rheumatic fever suggest that the usual point of entrance of the virus is the tonsil or the pharynx. The observations of Poynton and Paine, especially the experimental evidence, appear so complete as to be convincing. We require further confirmation of these observations before the microbic theory can be said to be established beyond dispute, but Osler and Allchin have boldly transferred rheumatic fever to the category of acute infectious diseases. If confirmed, as I believe these researches will be, what a valuable aid they will be to the precise understanding of the pathology of rheumatism. When the seed is fully identified we may hope to learn from its life-history outside the human body means for the prevention and treatment of this disease.

But I wish to point out that if the bacterial nature of rheumatic fever is fully established the patient work on the clinical side will not have been thrown away, that we shall still have to take account of the soil no less than of the seed, and, as in tuberculosis, the personal factor will remain as important in the future as it has been in the past. If the bacterial nature of rheumatism is conclusively proved we shall still have to take into account individual liability to the disease and to recognise that whilst some persons exposed to wet and cold, especially when combined with fatigue and exhaustion, escape, others similarly exposed are prone to contract rheumatism. Of course, it is well known that many cases occur without such exposure. But Pasteur, Wagner, and others have shown that by exposure to cold fowls (naturally immune) become susceptible to anthrax infection, and Monti has demonstrated that dogs, naturally more resistant than man to the pneumococcus, are taken ill and die from pneumococcic infection solely when they are inoculated after giving them a very cold bath. These facts are suggestive in connexion with the microbic nature of rheumatism. We shall continue to find that the predisposition runs in families and is usually inherited. We shall, in fact, find that the soil is no less essential for the production of rheumatism than is the seed.

APPENDICITIS, OR PERITYPHLITIS.

Appendicitis, or perityphlitis, offers an interesting and instructive study, clinically and pathologically, in connexion with the theme which we are considering. From being regarded, as it was when I commenced the study of medicine, as a rather rare condition it has come to be regarded as a very common one not only by the profession but by the public. Whilst the less acute or less severe forms have been recognised for a long time we have in recent years learnt that the very acute and fulminating cases due to ulceration and sloughing of the appendix causing abscess and perforation account for a great many obscure cases of peritonitis, the nature of which was unsuspected and misunderstood. The increase of our knowledge on the subject has reached a high degree of precision through the observations of the surgeon, the pathologist, and the bacteriologist. It was, I believe, Sir Samuel Wilks who, in the first edition of his work on Morbid Anatomy and Pathology, emphasised the fact that in inflammation and abscess in the right iliac region—perityphlitis—it was usually the vermiform appendix that was at fault and not the cæcum as was then generally taught. To the surgeons in this country and in America we owe the great extension of our knowledge that in inflammatory affections of the abdomen the appendix was at fault with a frequency not previously imagined and they have pointed out the anatomical conditions in the appendix that favour and predispose the appendix to disease. The bacteriologists have determined the micro-organisms that play such an important rôle as the excitors of the inflammation and its consequences in the appendix. Thus, on the one hand, we have learned that micro-organisms are always concerned in the inflammation, ulceration, sloughing, and necrosis that occur in appendicitis. The bacillus coli communis appears to be the most common—a bacterium in ordinary circumstances saprophytic and harmless but which may become virulent and deadly when growing in diseased tissues. More rarely the pus cocci, the streptococcus pyogenes, the staphylococcus, the proteus, and bacillus pyocyaneus are concerned, and the bacillus typhosus has been found to be the organism at fault. On the other hand, we have learnt that peculiarities of position and anatomical formation of the appendix and its mesentery tend to produce contortions and contractions and interference with the circulation in the appendix which prevent the discharge of its secretions, favour the formation of fæcal concretions, and prevent the expulsion of foreign bodies accidentally entering its canal. In one of these ways the vitality of this portion of the intestinal tract, probably owing to its being a vestigial remnant never so high as other parts of the intestine with active functions to perform, becomes impaired. The organisms in the appendix find a medium which enables them to grow and to multiply, often with intense virulence, by which they inflame or destroy the appendix and pass through its walls to the peritoneum and other contiguous parts. Sir Frederick Treves tells us that "it is impossible not to be struck with the fact that perityphlitis runs often in families," not so much as an inherited disease as a family disease. It is much more frequent in the second and third decennia and in the male sex.

So we find the seed and the soil in appendicitis the excitors of active disease and the predisposing conditions—the personal factor in this disease—each essential for its occurrence. But whereas in tuberculosis and rheumatism we are often able to detect the mischief by the history, the patient's appearance, the evidence of individual predisposition, there is nothing in appendicitis that reveals a tendency to this condition until the occurrence of an attack of appendicitis. Moreover, whilst the tendency to most of the infective diseases is a general one more or less distributed throughout the system, though in each there is a favourite mode of entrance of the virus, here it is an entirely local one extending over an area of only a few inches.

Reviewing the group of diseases which I have selected to illustrate my thesis we have seen that in each there are two factors—the soil and the seed, each necessary to constitute the disease, but that the relative share which they appear to take varies in importance in different diseases. We as practical physicians have to obtain our knowledge as to the micro-organisms concerned in these diseases and their chemio-physiological action from those who devote themselves to these studies, whilst we have to observe the effects of the micro-organisms on the human body and how the body reacts to the germs of the disease. The infective diseases existed long before the discovery of the germs and we have accumulated a large store of knowledge of the clinical course, the treatment, and the issue of these diseases. This accumulated experience is of great value though apt to be overlooked by the keen interest excited by fresh discoveries. It is against this tendency that I wish to enter a protest and to point out that what is true is not necessarily new We must never forget that the *soil* is of as great importance to study as is the *seed* in the proper understanding and treatment of diseases of microbic origin.

HEALTH OF ST. IVES.—Mr. J. M. Nicholls, the medical officer of health of St. Ives, Cornwall, in his annual report for 1901 states that 197 births were registered during the year, corresponding to a rate of 29·41 per 1000 The deaths numbered 129, equal to a rate of 19·26 per 1000

A Clinical Lecture

ON A CASE OF

SUPPOSED INTESTINAL OBSTRUCTION, DUE TO A VASCULAR LESION,

RAPIDLY FATAL FROM INCIPIENT GANGRENE OF THE STOMACH AND THE DUODENUM.

Delivered at St. Mary's Hospital on Feb. 25th, 1902,

BY HERBERT W. PAGE, M.C. CANTAB.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—I promised you a fortnight ago that I would tell you something about a remarkable case of intestinal obstruction which had been under my care recently. The case was one of singular interest and as far as my researches have carried me I believe it to have been unique. You will hear that there was no true intestinal obstruction at all, but nevertheless the case must be so described, for intestinal obstruction was a prominent feature of it and it was intestinal obstruction that I was called upon to relieve. Were I to ask you for the causes of intestinal obstruction you would doubtless be readily able to give me a list, as, for example, obstruction by band, by volvulus or kink, by growths which narrow the lumen of the bowel, by impaction of a foreign body, by accumulation of fæces, by any form of strangulation whether external and visible or internal and out of sight, and these various conditions you might speak of as true causes of obstruction in that they severally interfered with the lumen of the bowel and prevented the onward passage of its contents. And if I pressed you further you might remember other causes which rather may be regarded as those of false obstruction in that there is no mechanical interference with the lumen of the gut—the paralysis of bowel, for example, such as you may meet with from sundry nervous conditions, or the distension which may arise in the course of peritonitis when all peristalsis has been lost. Your list would be fairly complete, but I doubt whether you would think of vascular lesion alone as being a possible cause of intestinal obstruction. And yet there have been cases recorded from time to time where a vascular lesion—thrombosis of the superior mesenteric vein, for example—has given rise to symptoms of intestinal obstruction for which operation has been undertaken. I shall presently refer to a case of this sort which was brought before the Clinical Society of London by Dr. J. Rose Bradford and there have been other cases like it.[1] We ought, therefore, to have this cause of intestinal obstruction in mind, although from its exceeding rarity we may hardly expect to meet with a case ourselves. Now let me tell you of my own case.

On Monday, Feb. 10th, I was sent for by my friend and former house surgeon, Dr. J. A. Wright, to see a patient with intestinal obstruction and to come prepared to operate. I went and this was the story which I was told. The patient, a man aged 50 years, thin and spare, had enjoyed the best of health until three and a half years previously, when he had a very bad attack of typhoid fever which kept him in bed for some 10 weeks and which was complicated by thrombosis in the right leg. His health had never been the same since; he had lost his former strength and his capacity for continuous work. In the summer of 1899 he had thrombosis in the left leg following a bicycle accident and again in the spring of 1901 he was laid up for a month with thrombosis of the left femoral vein. I ask your special attention to these several attacks of thrombosis for they go far to explain his present illness. A week previously he had had rather a bad cold and had stayed indoors, but on the afternoon of Feb. 9th (Sunday) he was able to go out for a country walk. During the walk he was suddenly seized with pain above the umbilicus and this was soon followed by diarrhœa. As a matter of fact he had to relieve himself behind a hedge more than once, and the pain continuing he was obliged to rest in a cottage. Here the pain continued and the diarrhœa was more profuse. In about an hour he was able to get home and Dr. Wright first saw him at half-past five o'clock. The diarrhœa had then ceased and the pain was less, but there was much uneasiness or discomfort in the epigastrium and he felt as if he must be sick. He was cold but was not collapsed. At 9 P.M. when Dr. Wright next saw him he was restless and had considerable epigastric pain. He had vomited a little. Flatus had been passed from the bowel. Abdominal examination was negative. A subcutaneous injection of morphine and atropine was administered. The night was broken and he had occasional vomiting of a small quantity of odourless coffee-coloured fluid. There was some hiccough. Before daylight there was a return of the epigastric pain and at 6 A.M. the injection was repeated. At 10 A.M. he was fairly easy, but he still had epigastric pain and there was slight tenderness. The pulse ranged from 90 to 100. The temperature in the axilla was normal. Abdominal examination was again negative; there was no distension whatever. A rectal examination discovered nothing and a soap-and-water enema was entirely without result. At 1 P.M. Dr. Wright detected some resistance and tenderness midway between the umbilicus and the left costal margin and these became more marked in the course of the afternoon. The other symptoms continued and no flatus was passed. The pulse rose to 120.

---

[1] Notably since this lecture was given the case of "Intestinal Obstruction due to Embolism of a Branch of the Superior Mesenteric Artery" brought before the Clinical Society of London by my friends Dr. W. J. Tyson and Mr W. W. Linington of Folkestone, on April 11th (see THE LANCET, April 19th, 1902, p. 1109). Coffee-ground vomit was there also a prominent symptom.

I saw the patient soon after 7 P.M. It was obvious at once that the man was extremely ill, and from his aspect alone I formed a grave prognosis His pulse was then 108 and it was occasionally intermittent; he was vomiting copious quantities of the coffee-coloured liquid. The abdomen, which was absolutely flaccid, moved on respiration and was free from all suspicion of tenderness save only between the umbilicus and the left costal margin where were the resistance, the slight fulness, and the tenderness which Dr. Wright had described. It was clear that operation, if to be undertaken at all, could be delayed no longer. And I must tell you frankly that I never undertook an operation with less idea as to what could be the matter. Every conceivable lesion had been turned over in our minds: Dr. Wright himself even went so far as to suggest embolism of an intestinal vessel. A kink from former typhoid ulceration was one of the more unusual things which occurred to us, but from the symptoms and history the seat of probable obstruction was presumably high up in the intestinal tube, while kink the result of typhoid fever would rather be low down. It was under these unsatisfactory conditions that I opened the abdomen in the middle line above the umbilicus. A remarkable state of things was immediately disclosed. The stomach was seen to be enormously tense and distended, dark purple in colour, with here and there small flakes of lymph upon its surface, and conveying the impression that it would not bear much handling. Had it been a piece of gut exposed in operation for strangulated hernia I unquestionably should have hesitated to return it to the peritoneal cavity, for it had all the appearances which indicate approaching gangrene. It was suggested to me that I should puncture the stomach and let out the contents, but I felt that this would be a dangerous procedure as there might be difficulty in closing the opening. My search was next directed to the discovery of some cause for the supposed obstruction, and the bowel, large and small, was therefore systematically examined from end to end. Both large and small were found to be empty; I may say, in fact, that I have never seen small bowel so completely collapsed. Tracing it upwards no cause of obstruction was anywhere to be found, but as we approached the stomach so did collapsed bowel of natural colour gradually merge into distended and discoloured bowel until at its union with the pylorus the duodenum was seen to be enormously dilated like the stomach, and here, also, it had the purple colour and structural change which have already been described in the stomach itself. Satisfied that there was no mechanical cause for obstruction and that none could possibly have been overlooked, there was nothing left to us but to close the wound The condition of the patient was now extremely grave; there was profuse vomiting, and at one time we thought that he must die on the operating table. Happily that was obviated and he rallied sufficiently to talk to his friends. He died three hours afterwards.

We had now little doubt in our minds that a vascular lesion was at the root of the patient's symptoms and of the singular state of things which we had seen in the stomach and the duodenum. And here I am sorry to tell you that our story is incomplete. A partial necropsy was made by Dr. Wright through the operation wound and if you think of the difficulties of a necropsy unassisted in a country house it will hardly surprise you that the post-mortem record is not as complete as we could wish. Nevertheless, very valuable information was obtained and I will read to you Dr. Wright's notes. "The parts," he says, "looked very much the same as at the operation. I took out the whole gut, beginning at the sigmoid flexure. It was practically empty and collapsed until the beginning of the duodenum was reached. There was no obstruction whatever to be found at this or at any other place, but from it to the cardiac end of the stomach the whole length was hugely distended, even the pylorus being dilated. On opening the stomach there were about two pints of the dark, fluid, altered blood. The stomach and duodenum were stained with it, but none of the fluid had passed any further downwards in the intestine. There was certainly some difference in the mucous membrane of the stomach and duodenum as compared with the rest of the gut. The stomach-wall was greatly stretched, the veins were engorged, and on its anterior surface there was very slight superficial ulceration. Running here and there were some peculiar raised patches which looked most like thickened tortuous blood-vessels. I searched very carefully for arterial clot but could find nothing to swear to." In answer to further inquiry Dr. Wright told me that there was certainly no plugging of the portal vein itself.

This, then, is all the post-mortem evidence which I can give you, but yet I think there is hardly room for doubt that a vascular lesion was after all the real cause of the symptoms and of the state of the stomach and duodenum. Nothing else could well have accounted for them. I will give you the reasons for this conclusion.

First, there is the evidence of other cases of a like kind, and here I cannot do better than tell you of Dr. Rose Bradford's case,[2] entitled, "A Case of Thrombosis of the Superior Mesenteric Vein causing Intestinal Obstruction." A man, 20 years of age, was seized in the night with pain in the upper abdomen and he felt sick, but he was able to go to work in the morning. He was worse on the second day and on the third day he had diarrhœa. Then he took to bed. On the sixth day he went to University College Hospital and the summary of his history from that day to the eleventh day is in these words: "Since admission patient had remained in much the same condition, complaining of a good deal of abdominal pain, especially at the umbilicus and between this and the costal margin. The abdomen is not distended; if anything it is slightly retracted. There is no marked tenderness on palpation. Patient has had slight occasional vomiting of the contents of the stomach and the bowels have not been opened without enemata, but with these normal motions have been obtained." The scene then changed. The man began to vomit frequently and on the thirteenth day the pain was still more severe and the vomit, which had become incessant, was distinctly stercoraceous. He was worse on the day following and "it was decided to open the abdomen as it was thought that there was some form of intestinal obstruction." A piece of the small intestine about a foot long was found to be greatly swollen and thickened and purple in colour. There was no volvulus and no constricting band was found. There was a little reddish fluid in the peritoneal cavity and a little lymph on the intestine. The patient did not survive the operation long and at the necropsy "a coil of small intestine at the upper part of the jejunum was seen to be dark-purple in colour and considerably swollen and thickened for a distance of about 18 inches. There was no band or other cause of strangulation. The mesentery was thickened and the veins were obviously thrombosed. The trunk of the superior mesenteric vein was greatly thickened, the wall of the vessel being as thick as the wall of the superior mesenteric artery. The vein contained flakes of coagulum adherent to the inner surface and forming an almost continuous layer of decolourised blood-clot. The lumen of the main vessel was filled with reddish puriform material. The upper part of the vein was occupied by firm, partly decolourised, clot. The disease of the superior mesenteric vein extends into the main tributaries of this vessel—to a varying extent, however, in different ones. As the intestine is approached the thickening of the walls of the veins becomes less and less marked, until in most of the terminal branches the walls of the veins have their normal thickness and appearance." Those are the chief facts and I need not quote more, for they are sufficient for my purpose, which is to show you that plugging of a superior mesenteric vein may lead to symptoms suggestive of intestinal obstruction and that operation may be undertaken to discover and relieve the condition in the absence of any certain diagnosis. Were there no other cases of the kind, this case recorded by Dr. Rose Bradford would of itself be sufficient to suggest that a similar vascular lesion must have been present in our case. The patient's own history is, however, not less suggestive. You remember that on three previous occasions he had had attacks of thrombosis, and whatever may be the causes of blood-clotting in veins I think we may say that in some way or other this man was predisposed to the same thing again. The suddenness of onset, moreover, of the attack on this last occasion was very suggestive of a sudden vascular lesion and I venture to think that nothing else could possibly have produced in so short a time as 24 hours the striking changes which were found in the stomach and duodenum. I believe, moreover, that venous rather than arterial thrombosis must have been the cause of the impending gangrene. Dr. Wright has told us that he searched carefully for arterial clot but found none. *Furthermore, the valves of the heart* were healthy and free from vegetations from which an embolus might have been detached and lodged in some vessel. I hold, therefore, that we are justified in the conclusion that venous thrombosis was the actual disease and that we may regard the coronary vein and its tributaries, and in all probability the pyloric vein also, as having been the vessels affected.

---

[2] Transactions of the Clinical Society of London, vol. xxxi., p. 203.

It will interest you to know that an excellent account of all the conditions pertaining to thrombosis is to be found in Allbutt's "System" from the pen of Professor Welch. This is accessible to you in the library, but I will read one short passage which bears upon our present case:—"The symptoms"—he is writing of thrombosis of the mesenteric veins—"are the same as with occlusion of the mesenteric arteries, but as a rule are even more violent and rapid in course. They are as follows: sudden onset of very intense, colicky, not definitely localised, abdominal pain; distended, tender, tympanitic abdomen, vomiting which may be bloody; obstipation, or bloody diarrhœa; and rapid collapse, with cold sweat and subnormal temperature. The diagnosis is likely to be acute ileus and laparotomy to be performed. Death generally occurs within two or three days. The symptoms may, however, be less violent and the course less rapid than those mentioned. At the autopsy are found hæmorrhagic infarction and gangrene of the intestine, hæmorrhages in the mesentery, bloody fluid in the peritoneal cavity, and sometimes, although not regularly, peritonitis The cases without symptoms have been usually thromboses of slower formation, but this does not appear to have been always the case."

Such, gentlemen, is the story which I bring before you. A consideration of it is not likely, I fear, to lessen the difficulties which beset the diagnosis and treatment of intestinal obstruction. Of all the conditions which may present themselves at operation this surely of which I have spoken is the least amenable to relief. Nevertheless I commend it to your notice preparatory to the wider publication which I think it deserves

I am indebted to Mr Arthur E. Fidian for shorthand notes of this lecture

THE CONGENITAL FACTOR IN HERNIA.[1]

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,

SURGEON TO THE ALFRED HOSPITAL, MELBOURNE; LATE SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

IT may perhaps be within your memory that at the last meeting of our congress at Brisbane I contributed a paper to the transactions of this section entitled, "The Etiology and Treatment of Inguinal Hernia in the Young,"[2] and I placed before you certain important conclusions at which I had arrived in respect of the etiology of inguinal hernia in young children. My operative experience of 60 cases was very small, it is true, when compared with the enormous series that are frequently placed before us by surgeons at the present day; but I would point out that my series was an indiscriminate one, comprising an unbroken record of every case of inguinal hernia that had come into my hands during a certain period, and that the evidence afforded by an indiscriminate series of 60 cases when that evidence is unanimous is more weighty than any evidence that could be deduced from 600 cases that have been selected by reason of certain clinical characters that were deemed to call for operation.

The conclusions at which I arrived and which I believe to be of fundamental importance for a clear understanding, not merely of inguinal but of all other forms of abdominal hernia, I will set forth in the following propositions:—1. Oblique inguinal hernia is invariably caused by the presence of a congenital sac which in the vast majority of cases is provided by patency of the whole or a portion of the processus vaginalis. 2. There is no evidence in favour of the view that congenital weakness of the abdominal wall in the inguinal region is a factor in the causation of inguinal hernia. 3. While actual weakness of the abdominal wall in the inguinal region is frequently met with and is an *occasional* cause of recurrence after operation, such weakness is not congenital but is an acquired weakness due to the existence of the hernia and the use of a truss during a lengthened period. 4. Complete removal of the sac, when performed before the abdominal wall has sustained such damage, will not be followed by recurrence. 5. The causes of recurrence after operation are three in number—viz., (1) the above-mentioned acquired weakness; (2) incomplete removal of the sac; and (3) traumatism, the result of misguided methods of operating

These, then, are my articles of faith; the arguments on which they are based have been already published very fully[3] and I do not intend to trouble you with them again. The only new argument that I will bring forward to-day, if you will be so courteous as to regard it as an argument, is this. My former series of 60 cases has in the last two years been extended to well-nigh double that number, with the result that so far from having observed anything to shake my belief my confidence in the truth of the foregoing statements has been redoubled. To-day I will ask you, whether you agree with me or not, to assume for a few minutes that my views are correct, for I wish to suggest to you that they apply equally to inguinal hernia in the adult—that there is no difference etiologically between the inguinal hernia of children and that of older people and that the management of the affection in either case will be the same in principle, differing somewhat in detail but differing only by reason of certain factors that are often imported into the case of the adult but from which the young child is free.

When hernia has existed for some years the inguinal canal becomes converted into a large hole in the abdominal wall, because the curved fibres have been stretched, atrophied, and displaced during a period of years and are quite incapacitated from performing their natural function as the inguinal sphincter. This leads me at once to draw your attention to one of the singular and fundamental errors that have pervaded the whole theory of inguinal hernia. The belief is almost universally held that inguinal hernia is often the result of some congenital weakness of the inguinal abdominal wall which permits the descent of a rupture. This generally accepted view is the exact converse of that which I believe to be the truth, for instead of the weakness being congenital and the hernia consequently acquired it is the hernial sac that is congenital and the weakness that ultimately becomes acquired. It is of the utmost importance that this fact should be appreciated, for its teaching, when reduced to practice, means that if on the first occurrence of hernia the sac be removed the abdominal wall will thenceforward be unimpaired and the patient will be no more predisposed to recurrence than he would have been if he had never had a congenital sac and had never had a hernia.

Let me illustrate this point by citing the case of a man, aged 24 years, who became suddenly ruptured while playing football in August, 1899 At the operation four months later the bowel was found to have entered one portion of a bilocular congenital sac; the entire sac was ligatured at the neck and removed after incision of the external oblique aponeurosis but no attempt was made to close the canal by sutures. The patient was kept in bed for a fortnight and was told to exercise caution for a month afterwards; after that he was allowed to return to his arduous work and to indulge without stint in athletic exercises. For the last two seasons he has been as distinguished in the football field as he was before the operation and is one of the best forwards in a football team. I have quoted this case in order to illustrate a point, which is this—the sac was unquestionably congenital and was the essential cause of the hernia, no matter what the immediate cause might appear to be, and simple removal of the sac was efficient in curing the hernia absolutely. We quite discarded any theory as to the local weakness of the abdominal wall; but please to note that the condition that warranted us in discarding that theory was the fact that the hernia had existed for only four months—too short a time for any very serious damage to result to the abdominal wall from its presence. But supposing that instead of four months four years had been allowed to elapse, then we should have had no such confidence and the precautions against recurrence that would have had to be adopted would have been much greater and more extended in time, for some local weakness of the abdominal wall would certainly have been acquired. Again, supposing that instead of for four months or for four years the patient had worn a truss for, say, 40 years; at the age of 64 years there would have been a gaping aperture in the abdominal wall which would manifest no tendency to close after the sac was removed; it would then be closed by Bassini's method which in my opinion is by far the best of its kind, but the assurance of success would be much diminished. Furthermore, I think that were such a case presented to us just now some of us might receive with incredulity an assertion that the sac was congenital.

[3] THE LANCET, Nov 18th, 1899, p. 1353, and Oct 20th, 1900, p 1123

Among the children upon whom I have operated—some 115 in number—I know of only two in whom there has been anything in the nature of a recurrence. In both these cases the recurrence consisted in a slight yielding of the abdominal wall, the result of the acquired weakness. Both occurred two or three months after the operation and both were remedied by the use of a light truss for three months. One patient was a boy, aged 10 years, who had worn a truss from infancy and he brought about the recurrence through attempting some acrobatic feats; the other, a child five years of age, fell out of a tree on to his stomach. In cases where a truss has been worn for any length of time such severe tests as this should be carefully guarded against for 12 months, after which I think it probable that the inguinal canal will be safe, especially in the case of a growing child.

The laxity of the peritoneum in the neighbourhood of the inguinal region is a matter to which I have not previously alluded, although it plays an important part both in respect of the incidence of hernia and of its operative treatment. Physiologically it is of course adapted to meet the requirements of the bladder in its varying conditions of collapse and distension. To this laxity of the peritoneum we owe several things. In the first place, we are largely indebted to it for the occasional occurrence of direct inguinal hernia in young people—a rare affection which would, I think, be impossible were it not for the voluminous arrangement of the peritoneum at this place. It would seem that this form of hernia can occur suddenly and independently of the presence of a pre-formed sac, in which case it is probably the only form of abdominal hernia that can do this and it will therefore be the only form of hernia to which the time-honoured name of "rupture" can properly belong. In the course of operative treatment, however, the looseness of the peritoneum stands in good stead, for it enables the operator to pull down the neck of the sac so as to bring it easily within reach when he desires to apply the ligature. But there are certain circumstances that interfere with the application of the ligature to the neck of the sac and these are of great importance and, strange to say, they have been sadly overlooked by writers on hernia. There are two such conditions to which I will refer—(1) the close relationship of a portion of the bladder to the neck of the sac; and (2) hernia of the sigmoid flexure on the left side. I have elsewhere called attention to the frequency with which the bladder, or a diverticulum from it, has been seen at the neck of the sac in operating for hernia in children; and of late I have seen with increased frequency a portion of that viscus in operating upon adults. Now, it is obvious that where the bladder intrudes its presence at the neck of the sac the application of a ligature at the surgeon's seat of election will be interfered with. I have found, however, that in such a case the bladder may be quite easily peeled off the sac—a proceeding that is facilitated by the introduction of the index finger into the latter structure.

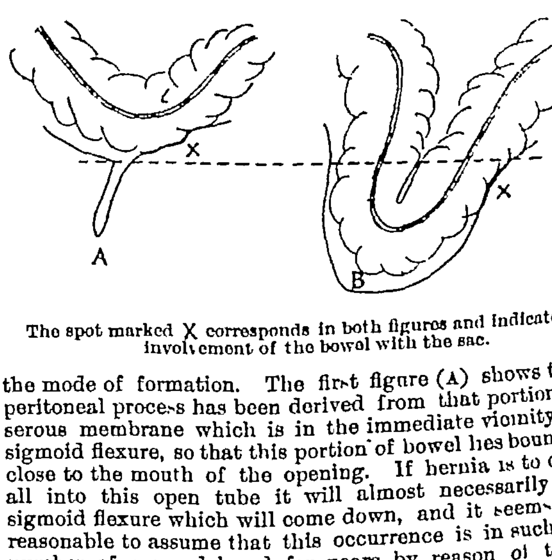
It appears to me that a great deal of unnecessary mystery has been imported into the subject of hernia of the bladder, the etiology of which is quite simple, and, further, I do not think that it need ever be a serious obstacle to the satisfactory clearance of the inguinal canal. In a word, I see no reason to doubt that hernia of the bladder is always secondary to an ordinary hernia and is an accidental result of the dragging down of the vesical peritoneum through the hernial orifice.

I come now to a form of inguinal hernia which presents points of similarity to hernia of the bladder—hernia of the sigmoid flexure on the left side. I cannot understand how the importance of this variety of hernia has come to be so under-estimated by authors. In my experience it has proved to be of remarkable frequency and it requires very special management, in default of which recurrence is almost sure to take place. Yet, strange to say, on consulting authorities I find only the most cursory allusion to it and nowhere have I found any adequate description of an appropriate mode of dealing with it. In this variety of hernia part of the peritoneal reflexion which invests the sigmoid flexure enters into the formation of the sac, so that a certain portion of the sac is intimately connected with the gut. It therefore becomes impossible to ligature and to remove the sac in the ordinary way; while to be content merely with removing the free portion of the sac and to push the upper portion of it with the attached bowel back into the abdomen would be to perform a very imperfect operation and to court failure, no matter what ingenious device might be adopted with the vain and futile purpose of fortifying the abdominal wall and closing the canal by sutures.

With regard to the etiology of this form of hernia it appears to me a most remarkable circumstance that all authors seem to agree that it is of congenital origin, while they say really very little about it. Now I hold that all forms of oblique inguinal hernia are of congenital origin, but the only form that has given me pause and caused me some hesitancy is this particular form which we are discussing. Why surgeons who believe that inguinal hernia is commonly acquired should look upon this form of all others as congenital I am at a loss to conceive, for the truth is that it is met with only very seldom in childhood but very frequently in adults. In 115 operations for hernia in children I have met with this variety of hernia only once, while in a relatively inconsiderable series of adult operations I have met with it three times. The ages of my patients have been 2, 22, 32, and 68 years. With respect to the etiology of this condition I have no doubt whatever that it is fundamentally the same as that of all other varieties of inguinal hernia and that we must look to the presence of a congenital sac in the inguinal canal, which is probably always in this case a portion of the processus vaginalis unclosed.

These two diagrams (Fig. 1, A and B) will serve to indicate the mode of formation. The first figure (A) shows that the peritoneal process has been derived from that portion of the serous membrane which is in the immediate vicinity of the sigmoid flexure, so that this portion of bowel lies bound down close to the mouth of the opening. If hernia is to occur at all into this open tube it will almost necessarily be the sigmoid flexure which will come down, and it seems not unreasonable to assume that this occurrence is in such a large number of cases delayed for years by reason of the substantial nature of the large bowel and its fixation close to the neck of the sac rendering it less favourable to protrusion than would have been the case if the smaller gut was presenting. The second figure shows what happens when the

FIG. 1.



The spot marked X corresponds in both figures and indicates the involvement of the bowel with the sac.

bowel does at length descend into the sac. By reason of its attachment to the peritoneum at the mouth of the sac this portion of the peritoneum is subjected to traction such as could not be exerted by a herniated portion of small bowel, and as the peritoneum in this neighbourhood is lax and voluminous it readily becomes dragged down in such a way as to produce the condition which we are considering. The correct management of this kind of hernia is of great importance and it is very simple. The portion of the sac to which the bowel is attached should be cut away from the remainder and returned into the abdomen with the gut; this is effected by running the scissors up on either side of the prolapsed gut as high as possible, and after the bowel has been returned the remainder of the sac may be ligatured and removed in the ordinary way. Of my cases, the man aged 68 years had worn a truss for 30 years; the hernia was very large and irreducible; the opening in the abdominal wall was enormous and was closed by Bassini's method. The man aged 32 years, who was an officer in the merchant service, and the child were both treated by simple removal of the sac as I have just described. All three were operated upon more than three years ago and all are free from recurrence. The man aged 22 years was operated upon only three months ago. In all the adults the canal was opened up by incision of the external oblique aponeurosis; in the case of the little child I considered this step unnecessary.

Whatever divergence of view there may be as to the part played by the congenital sac in inguinal hernia, when we turn to femoral hernia there would at first sight appear to be no room for doubt. All authors are agreed that femoral hernia is always acquired; the anatomy of it is simple and there is no funicular process to complicate matters, so that it would appear as though I was on safe ground when at Brisbane I made the following allusion to the subject: "Femoral hernia is the type of the true acquired hernia. The anatomical structures concerned are eminently favourable to it; the clinical manifestations are consistent with it, and they are consistent with nothing else. .... To put it tersely, in femoral hernia it is the hernia that forms the sac; in inguinal hernia it is the presence of a sac that causes the hernia." I am glad now to find that in the succeeding sentences I indicated some doubt as to the absolute truth of the foregoing statement, for since we last met, three years ago, I have entirely changed my opinion as to the etiology of femoral hernia. I now believe that, like inguinal hernia, femoral hernia is caused essentially and typically by the presence of a congenital sac in the crural canal, and the question as to which I am in some doubt is not whether femoral hernia is ever of congenital origin, but whether it is ever truly acquired.

In order to arrive at the explanation of the congenital sac of femoral hernia we have to go back to the second month of fœtal life, at which period the appearance of bud-like processes, four in number, on the surface of the embryo signalises the commencing development of the limbs (Fig. 2). A section made of one of these limb-buds and the adjacent body wall (Fig. 3) will show the parietal layer of the mesoderm throwing out its bud, which is covered by the ectoderm externally and lined internally by a specialised layer of its own cells, which become flattened and ultimately develop into the endothelial cells of the peritoneum. Now, it would seem that all the important changes in the development of the embryo are accompanied by the development in the evolving structures of a vascular system, at first absolutely simple and direct in plan, but which, through having to follow the varying contortions of the developing mass, becomes likewise contorted and apparently eccentric in arrangement. I imagine that every artery and every portion of an artery in the body, no matter how tortuous its arrangement may be now, at its inception took the shortest and most direct route from its origin to its termination; its course was, in fact, a straight line and the arterial tortuosities with which the dissecting-room has made us familiar may be regarded as an accurate though necessarily imperfect sketch-in-outline of the embryonic changes that have culminated in the full development of the organ to which the artery is distributed. This is most clearly seen in the larger arteries, especially those of the head and trunk, but wherever we find an artery taking a circuitous route or coming off from its parent trunk at such a point that it has, as it were, to retrace its steps in order to arrive at its area of distribution, we may safely take it as a guide to aid us in understanding what went on in the process of development. It will suffice to suggest as instances, taken almost at random, the peculiar windings of the pudic artery; and, again, no instance in the body is of more immediate interest than the developmental history attaching to the little ascending palatine branch of the facial which runs vertically upwards beside the wall of the pharynx, passes over the top of the superior constrictor, and then down again with the levator palati muscle on to the upper surface of the soft palate.

FIG. 2.

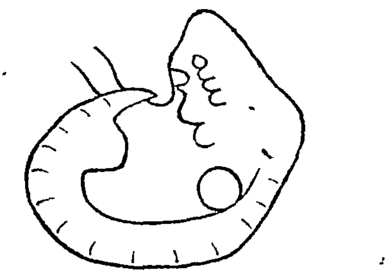


Diagram of embryo at about fourth week, showing commencement of limbs.

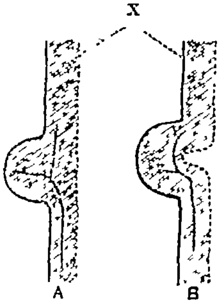
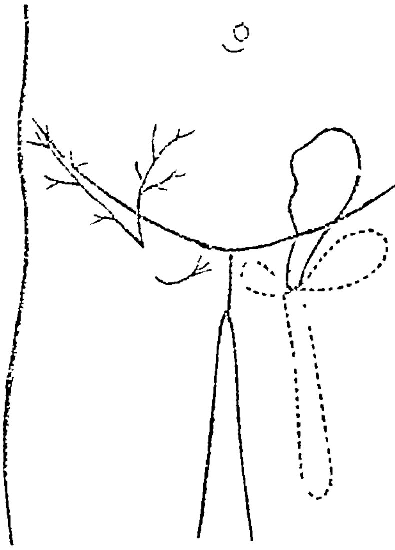
FIG. 3.



Diagrammatic section of posterior limb-buds; in B, formation of peritoneal pouch is shown. The shaded portion represents the mesoderm; the dotted lines the layer of cells destined to form the peritoneum. X, Abdominal wall.

I wish now to direct your attention to a group of humble little vessels, branches of the common femoral artery, the superficial circumflex iliac, the superior external pudic, and, especially as the most typical and useful for our purpose, the superficial epigastric which turns upwards across Poupart's ligament to be distributed on to the abdominal wall (Fig. 4). Why does it take this course? The reason will be at once evident when we refer to the first beginnings of a vascular system in the embryonic limb bud. The first branches that are given off from the main artery will be distributed to structures that are destined to form part of the abdominal wall, so that when in the course of development the groin becomes deepened, and the limb having become lengthened prepares to pass through an arc of about 145° or more to attain its permanent relationship with the trunk, it is at once seen how it comes about that the superficial epigastric artery and its companion follow the course that they do. Turning again to the diagram of the limb-bud it is easy to understand that in the initial steps of its development there is a distinct possibility that a little pouch from the wall of the pleuro-peritoneal cavity may be involved in the projecting process (Fig. 3, B). This is just the kind of developmental accident that is certain to occur sometimes, and when it does it is obvious that the future of this diverticulum will be subject to precisely the same influences that have determined the peculiar course and position of the superficial epigastric artery and its fellows. To put it plainly, the sac of a femoral hernia, when it turns upwards over Poupart's ligament or outwards towards the iliac spine, as it frequently does, occupies that position because it always has occupied it ever since the early embryonic period which witnessed the commencement of the limb. The fundus of the sac became accidentally involved with the abdominal wall then and the development of the limb and its assumption of its normal position have brought about such lengthening of the sac as obviously will be inevitable.

FIG. 4.



On the right limb are shown the branches of the common femoral artery; on the left the situation occupied by the large femoral sacs. The upper of these represents accurately the case described in this paper.

In cases of femoral hernia in which the sac simply protrudes at the saphenous opening, and they constitute the very large majority, the difference is simply a difference in the size of the sac—that is to say, at its origin the pleuro-peritoneal pouch was too short to become implicated with the abdominal wall.

Let us now see how our theory agrees with the observed clinical features of femoral hernia. It is well known that when femoral hernia attains a large size it has a tendency, after emerging from the saphenous opening, to turn upwards across Poupart's ligament, or more commonly upwards and outwards towards the iliac spine. Surgeons have never been quite satisfied with the theories that have been advanced to explain this circumstance; this is not very surprising, seeing that it has been found necessary to invent and to adopt erroneous explanations because the true one has been missed. There is no conceivable theory which will explain why in one case a large femoral hernia should pass upwards on to the abdomen, in another case downwards almost to the knee,[4] and in yet other cases outwards in the same direction as the circumflex iliac vessels or inwards and upwards to the scrotum or labium,[5] except the theory of congenital origin of the sac; and this explains it perfectly when we come to consider the mode of development of the limb and the variation in the ultimate destination of the sac that may be induced by slight accidental differences in position at the time of its inception. Assuming this view to be correct, the fact that in one case a femoral hernia will enlarge painlessly to a great size and in another will be unable to increase beyond the size of a walnut presents no difficulty; it is a question of the original size of the sac. The large hernia while it is steadily increasing in size is increasing not by gradual enlargement of the sac but by gradual lengthening of the mesentery. The long mesentery observed in hernia has been regarded, I believe quite erroneously, as a contributing cause of hernia, whereas it would appear with more probability to be the result of the presence of a large sac.

A few weeks ago I removed from a woman a large femoral sac which is accurately represented in Fig. 4. She gave the history that for six years it steadily enlarged and then for three years she wore a truss, so that it had existed nine years in all. During the six years while it was growing it gave her so little pain or inconvenience that she could tell me very little about it, it used to disappear when she lay down at night, but she never noticed how it disappeared or how long it took to do so; in fact, she took no intelligent notice of it whatever. Then eventually she consulted a lady practitioner who advised her to wear a truss, which she did for three years. When she came to me for operation there was no hernia to be seen, but the large sac filled with peritoneal fluid when she stood up without the truss, forming a large hydrocele on the front of the groin and abdomen. The case is a rare one but by no means without precedent. You will notice that a small loculus or diverticulum is shown (Fig. 4); this is a very commonly-seen feature of the congenital sac of the inguinal canal and is, I believe, an almost invariable accompaniment of imperfect descent of the testis, although it is often seen where the descent of the testis is perfect. As I have elsewhere pointed out it constitutes the anatomical basis of interstitial and pro-peritoneal hernia.[6]

I am afraid that I shall disappoint you if you look for the announcement of a royal road to the cure of femoral hernia based upon the theory of the congenital origin of the sac. The only effect upon our operative procedure, and that effect is one by no means to be despised, will be to cause us to abandon vain endeavours to block the crural canal or to close the crural ring by sutures or other device. The first step in the establishment of a sound method of treatment must always be to seize upon sound pathological principles to be our guide and the only deduction I am able to draw from the view that the femoral sac is congenital is that removal of the sac from the femoral canal is the essence of the treatment, that the fault lies in the presence of the sac and not in the construction of the canal, and that we are thereby directed to remove the sac and to leave the canal alone. How best to remove the sac I am a little uncertain. I have hitherto always contented myself with ligaturing the sac as high up as possible, but other methods for removing the stump from the neighbourhood of the crural ring have been suggested and are good in principle. But the point is clear that whatever means are adopted to achieve this object are certain to be more efficiently carried out if we quite understand that the essential feature of the operation is the removal of the sac and not any form of obstructive treatment applied to the crural canal.

I should like to add a very few words with reference to the occurrence of hernia in situations other than the inguinal and crural canals, such as the obturator and ischiatic foramina. Is there also a pre-formed sac in these situations? I may answer the question as far as I myself am concerned by saying that if I could believe that a hernia could pass through the obturator or ischiatic opening in the absence of a congenital sac I should scatter to the winds the views which I now hold on the subject of hernia and be prepared to believe anything. All our knowledge of the nature and capabilities of the intra-abdominal pressure and of the difficulty that it experiences in forcing a hernia even into a congenital sac forbids absolutely the belief that it could ever be enabled to force a piece of bowel or omentum through such small apertures as those which I have mentioned, pushing the peritoneum and fascia before it. On the other hand, the occasional presence of a pouch of peritoneum in these situations is not by any means a source of perplexity, but, on the contrary, is only what we might expect. Whenever structures like the obturator and ischiatic vessels, that inside the abdomen are in intimate relation with the peritoneum, pass outwards in the course of development it is easy to understand that occasionally a little of the peritoneum may be made to accompany them for a short distance; and I would suggest that if some of our pathological friends who have the opportunity of making large numbers of post-mortem examinations would examine these hernial orifices in a large number of bodies they would be enabled to make some very valuable and interesting observations with reference to this matter.

In conclusion, let me explain in a very few words why I have not troubled you with any statistics. This is not, I am happy to say, because there is anything for me to conceal or because they would show anything to weaken my contention as to the congenital origin of the hernial sac. If, however, there is one thing more than another with which I have been impressed by discussion of this subject it is the absolute inutility of mere statistics. Statistics are valueless and misleading unless we bring to their interpretation sound and correct pathological or etiological principles; but the principles must come first. If we put the statistics first and try to extract principles from them we shall not only fail but we shall certainly be misled. The reasons for this will be sufficiently obvious if you will think the matter out but I will not detain you by dilating upon them, for I have already occupied your time sufficiently. My aim has been to show cause and to afford a stimulus for a fresh scrutiny of the subject of hernia and I shall be well satisfied if this contribution to the proceedings of this section of the Congress should prove to be of some utility in furthering the rational and scientific treatment of one of the most common and important of the ailments with which we as surgeons are called upon to deal.

COMPLETE RELAXATION OF THE ABDOMINAL WALL UNDER ANÆSTHETICS.

BY J. BLUMFELD, M.D. CANTAB.,

ASSISTANT ANÆSTHETIST TO ST. GEORGE'S HOSPITAL; ANÆSTHETIST TO *THE GROSVENOR HOSPITAL.*

CASES of operation upon the abdomen are those, perhaps, which more severely than any other test the anæsthetist's skill in his endeavour to secure that condition of the patient which gives the greatest facility to the surgeon in his manipulations. In many cases much of the difference between an easy operation and a difficult one lies in the extent to which the anæsthetist has or has not secured a flabby condition of the abdominal walls and an absence of tendency to protrusion on the part of the intestines. In most cases such a state—the *ultima Thule* of the abdominal surgeon's desire—is obtainable if the proper anæsthetic, which is generally chloroform, is employed to the proper degree, which is generally a very deep one. There are, however, some cases in which this complete relaxation and quiet breathing are very difficult and others in which they are, I think, impossible of attainment. The reasons for such difficulty may be examined with advantage and the proper steps decided upon for overcoming it when possible.

The desired condition of the abdomen depends on three main factors: (1) absence of excessive respiratory vigour; (2) absence of contraction of the recti abdominal muscles; and (3) normal character of the respiratory movements. To *ensure the coöperation of these factors some purely physiological* considerations must be borne in mind. For it is the object of the anæsthetist to avoid in every way what is known to the physiologist as forced respiration. In normal breathing the tendency of the diaphragm to pull inwards the sternum and lower ribs has little effect. In forced inspiration, especially where there is any obstruction to the entrance of air into the lungs, the lower ribs may be so much drawn in by the contraction of the diaphragm that the girth of the trunk at this point is obviously diminished. By such contraction the epigastrium is affected. Similarly with expiration, even in normal breathing, the elastic return of the abdominal walls is probably accompanied and assisted by contraction of the abdominal muscles. When expiration becomes laboured *these muscles become important expiratory* agents. By pressing on the contents of the abdomen they thrust them and the diaphragm up towards the chest. In laboured respiration the expiratory events are especially augmented.

The activity of the respiratory centre is acutely affected by changes in the quality of the blood distributed to the medulla and by nervous impulses reaching the centre along various nerves or nerve tracts. The more venous the blood the greater the activity of the respiratory centre. Nervous impulses may increase or diminish the depth of breathing and may slow or quicken its rate. There is not, Foster says, an afferent nerve in the body which may not be the instrument of influencing the respiratory centre. Certain nerves are more closely connected with it *than others and the most conspicuous* and important are the vagi. It is easy to understand, therefore, why in abdominal operations more than in others there may be difficulty in securing quiet breathing. Influences which tend to stop inspiration tend to encourage expiration. This explains how it is that shallow breathing with its tendency to the stopping of inspiration is not always the most favourable for the surgeon. The depressed inspiration which does not of itself embarrass him is liable to be accompanied by exaggerated expiration and this being *effected by contraction of the recti* provides at once a hindrance. Thus usually the best condition is quiet but natural breathing, respiration which is certainly not more vigorous than usual but which is also not very much less so.

When the blood is more venous than normal—i.e., has less oxygen—as is shown clinically by cyanosis, then respiratory movements increase in force and frequency. If cyanosis continues the respiratory movements become more marked than the inspiratory. This is in accordance with the already-mentioned effect of improperly oxygenated blood upon the respiratory centre. The amount of oxygen taken up by the blood from the lungs depends partly on the richness of the blood in red corpuscles. A person who is feeble and anæmic *is poor in the oxygen-bearing red corpuscles.* The same applies to fat people. With such people, therefore, any deprivation of air—i.e., of oxygen—gives rise to laboured respiration unusually easily. For these physiological reasons the clinical practice is sound which in such cases supplies air—i.e., oxygen—as freely as possible with the anæsthetic. Consequently, methods are to be avoided with this class of case which necessitate limitation of air-supply. Closed instruments are not to be used, at any rate for any long period, and if *ether alone is employed it is to* be *given from* a cone open at the top or from some other form of apparatus, such as a Rendle's mask, that admits air freely. Ether given in this way is often of the greatest service during a long administration to a feeble subject. Purely physiological teaching, then, points the proper conduct for securing abdominal quiet just as surely as clinical observation. We must avoid all cyanosis and all obstruction to breathing and we must have an anæsthesia deep enough to prevent the respiratory centre from being readily interfered with by afferent impulses.

The worst difficulty is opposed to the surgeon's manipulations in those cases where the recti contract firmly with expiration, the edges of the muscles being clearly defined and the muscles *themselves rising up with every expiratory effort.* In such cases the ordinary rhythm of protrusion of the abdomen with inspiration and depression with expiration is altered and the abdominal walls appear more prominent with expiration than with inspiration. A similar alteration of the rhythmic variation in the abdominal wall occurs when respiration is mainly or entirely thoracic, as it is in some cases of abdominal disease. In these instances, however, the passive condition of the abdomen offers little obstacle to the surgeon. In some cases where the abdomen is much distended—by a large tumour in its upper part for instance—although breathing is entirely carried on by the chest, yet there is no drawing in, or expulsion of, the abdominal wall. The diaphragm is apparently unable to descend at all; the *abdominal wall is quiet and convenient for operation.* Without any undue contraction of the recti the surgeon may yet be much inconvenienced if the mere extent of the respiratory movements of the abdominal wall is too wide. This occurs in some subjects if too light an anæsthesia is maintained. More commonly it is due to cyanosis or some obstruction in one or other part of the air-passages. The commonest causes of such obstruction are falling back of the congested tongue, swelling of the tongue and fauces, and excess of mucus.

The two conditions of the abdomen, in fact, which have been described—viz., excessive natural movements and contraction of the recti—are in the vast majority of instances due to preventable causes. These causes of the unwished-for condition are (1) cyanosis, from whatever reason; (2) any obstruction of the air-way; (3) not enough anæsthetic; and (4) too much anæsthetic. Physiology explains plainly enough how the first two causes, cyanosis and obstructed air-passages, lead to alterations of respiratory movement which clinically are such a *hindrance to the operating surgeon.* Insufficient anæsthetic raises inconvenience by allowing too free movements, although there is not necessarily any alteration of the natural relationship between inspiration and expiration. Too scanty use of the anæsthetic may also be accompanied by spasmodic closure of the jaws, and this by a straining, gasping kind of respiration. Excessive use of the anæsthetic tends to trouble by causing cyanosis. The cyanosis may be of very slight degree and yet its removal may at once change a gasping respiration greatly impeding the surgeon into a condition of smooth breathing which allows his work to go on with perfect ease. Particularly in pale, feeble subjects, such as are easily amenable to anæsthetics, I have seen inconvenience arise simply from the administrator permitting a slight amount of cyanosis. On withdrawing the anæsthetic, slightly opening the mouth, and drawing out the tongue, I at once obtained a perfectly satisfactory condition. The slight cyanosis that occurs in these debilitated subjects is easily overlooked by the inexperienced.

The operations particularly in which the utmost possible quiet and softness of the abdomen are required are mainly, perhaps, those which are performed upon its upper regions and those upon the bladder. Thus, in operations for gastric ulcer and in those upon the gall-bladder and bile-ducts, &c., the surgeon may not only be delayed but almost prevented from carrying out his aims if there is any contraction of the recti or if the abdomen heaves extensively with every act of respiration. As a rule, the best way to anæsthetise these cases is by inducing anæsthesia with gas and ether and then changing early to chloroform. This is sparingly given at first, but as soon as the anæsthetist has properly gauged his patient's susceptibility it is pushed to a deep degree. Such a procedure is probably the only one by which the condition of greatest possible facility for the surgeon is obtained. It undoubtedly involves risk if undertaken by anyone who is not thoroughly familiar with chloroform from frequent use. Fortunately, in feeble persons whose general condition would make deep chloroformisation specially dangerous, the desired condition of abdominal quiet is usually obtained without very free use of the anæsthetic. In these cases it is often best to use ether with the chloroform in the proportion of two parts of chloroform to three of ether. Moreover, with such persons gas is to be used very sparingly and any closed apparatus is generally best dispensed with or used only for a few minutes at the beginning. It is sometimes best even to induce anæsthesia by the chloroform and ether mixture, continuing with this or with chloroform alone, ether being added if stimulation is found necessary. The mixture is given from a drop bottle on a Skinner's mask at first and afterwards a cone or Rendle's mask may be substituted. For all abdominal cases this mixture of chloroform and ether in the proportions of two-fifths and three-fifths is in my experience an admirable anæsthetic and has over A.C.E. the advantage of greater simplicity.

There are certainly some cases in which the best condition of the abdomen, from the operator's point of view, cannot be obtained by the use of ether alone. The use of a closed ether apparatus throughout a long abdominal operation, such as we are considering, is rarely advisable, and if for some particular reason this agent is to be used from first to last, anæsthesia, when once properly induced, should be maintained by the use of some partially open instrument or mask which admits air freely. The easiest conditions for respiration do not appear to hold while a closed apparatus is being employed even when, with Clover's apparatus, the bag is kept off.[1] A more open method of administration with free air-supply offers often a better chance of obtaining that perfect flaccidity of the abdominal wall which is the aim of the anæsthetist and the comfort of the surgeon.

The avoidable causes of difficulty arising from the state of the abdominal wall we may now regard as dismissed. When the reasons for their presence are thoroughly appreciated they will not be allowed to come into play. The causes of abdominal difficulty that are not so easily removed depend upon conditions peculiar to the abdomen of the particular patient. These conditions are: (1) the shape of the trunk as it affects the upper portion of the recti muscles; (2) the thickness of the abdominal wall, particularly if due to muscular development; (3) the pathological condition of the recti muscles due to underlying disease; and (4) to these may perhaps be added abnormal sensibility to reflex effects.

1. *The shape of the trunk* gives rise to difficulty when the costal arch is unusually steep or narrow and the upper part of the rectus muscle is therefore very slanting. Perhaps the most aggravated difficulty that I have seen caused in this way was in a woman, the subject of severe angular curvature, who underwent the operation of pyloroplasty. In this woman the respiration was quiet and there was no contraction of the rectus muscles, yet their peculiar conformation, due to the long narrow costal arch, certainly provided considerable obstacle to convenient manipulation on the surgeon's part. In other instances very steep upper portions of the rectus muscles have inconvenienced the operator. In such cases the muscles seem as if they were too tightly stretched between their upper and lower attachments. Can the inconvenience arising from such structural peculiarity on the patient's part be remedied by the anæsthetist? Obviously, no use of chloroform or ether, to whatever extreme it is pushed, can avail, for in the case under discussion there is no question of active muscular contraction. When the muscle-fibres are entirely free from contraction the muscles are still inconveniently on the stretch. The proceeding most likely to be of use is to alter the position of the patient in such a way as to approximate the upper and lower attachments of the muscles of the abdominal wall. Thus if the knees are bent and the pelvis is raised, and the hollow of the back is allowed to drop, the particular difficulty with which we are concerned might be materially counteracted. Whether the inconvenience caused to the surgeon by this altered position would not be worse than that which it is designed to overcome is another question.

2. *Mass of muscle.*—When the abdominal walls are thick, whether from fat or from high muscular development, the surgeon may be much inconvenienced. If the trouble is due to massive muscles the slightest contraction on their part may make the inconvenience formidable. In such case the anæsthetist will do his utmost for the operator's convenience by maintaining a very deep anæsthesia entirely free from cyanosis and from any obstruction to breathing. Most often chloroform or a mixture will be the best agent to employ. Occasionally ether freely given with plenty of air seems to be most suitable. It is often necessary to hold the lower jaw forward from behind each angle and frequently to sponge out any mucus from the pharynx in order to secure perfectly unimpeded breathing. Sometimes this is not enough and the jaw has to be *slightly* opened by a gag and the tongue well drawn forward before the desired abdominal quiet is obtained.

3. *Pathological condition of the rectus muscle.*—In certain cases of chronic inflammatory disease in the upper part of the abdomen—as, for example, gastric ulcer with much adhesion—the upper part of the rectus muscle is, I believe, in a condition analogous with that which is sometimes found in the contracted muscles around a diseased joint. There appears to be actually a shortening of the muscle fibres and in this condition no use of the anæsthetic, however complete, can effect the relaxation of the muscle. If there is not actual shortening at any rate there is such spasm as cannot be relaxed. It is well known that in some functional spasms—in some cases of spasmodic wry-neck, for instance, and in some hysterical contractions of the fingers—the contraction of the muscles becomes perpetuated. The spasmodic condition in such cases is sometimes not relieved even by deep anæsthesia. In the cases now referred to the contraction of the abdominal muscles may be of somewhat similar nature. It may be that the protective reflex contraction set up by underlying disease has persisted so long as to become permanent. It must be borne in mind, too, that the ease with which reflex contraction of muscles is dispelled by anæsthesia varies greatly. In certain subjects only the deepest available anæsthesia is of any use. Every anæsthetist has met with instances in which although he used his materials with unusual freedom reflex effects were produced by the surgeon's manipulations. Such instances are common when some part of the genito-urinary organs is the seat of operation. Another conceivable explanation—in cases, at any rate, where there is adhesion to the anterior abdominal wall—is that inflammatory products have actually become organised and shrunk within the muscle, thus producing permanent contraction. Such an explanation seems to be very feasible in such cases as the following. In this case, that of a woman who was suffering from severe chronic gastric symptoms, excellent opportunities were afforded of accurately noticing the condition of the abdominal wall under anæsthetics, for these were employed on two separate occasions, the first time simply for examination and the second time for an exploratory laparotomy. Before administration of the anæsthetic the abdominal wall,

[1] Dr. F. W. Hewitt's wide-bore inhaler has probably from this point of view a great advantage over the usual form of Clover's inhaler.

corresponding week of last year. The chief increase is in the Punjab where 10,525 deaths were recorded. Two cases have occurred in the segregation camp at Rangoon, both of which were imported from Calcutta. The disease has broken out in Quetta and has suddenly assumed great virulence at Hyderabad (Sind); it has also increased in Karachi; it is rising in Bombay and has developed rapidly in Calcutta. On the other hand, it is subsiding in Poona. The figures for the week are: Bombay Presidency, 5303 deaths; Bengal, 1101; Madras, 456; North-west Provinces, 2143; Mysore, 426; and Kashmir, 350. In Bombay city there were 750 deaths and in Calcutta 349. The rate of mortality in Bombay city is 109·5 per 1000. It is reported that at Hassan in the Madras Presidency the plague has completely exterminated all the squirrels. Hassan was formerly full of them. The inhabitants are encamped on the outskirts of the town

An important proposal has, it is understood, been submitted to Whitehall by the Government of India to improve Calcutta by means of wide thoroughfares. The work to be undertaken will comprise about 15 miles of improved roads and will be enormous. It is estimated to cost about one and three-quarter millions sterling in order to acquire the necessary property. A question at issue is as to who will find the money. The provincial authorities say that the work is imperial and that it should be undertaken by the Government of India, while the latter says in effect that Calcutta will alone be benefited and that Calcutta should pay. A proposal is made that the Secretary of State should sanction the municipal corporation raising at least 150 lakhs, which would be laid out by an improvement trust. The Government of India, it is said, offers from 15 to 20 lakhs. The hill stations have been largely helped by the Government of India; two-thirds of the cost of the Simla water-supply were paid by Government, and the protection works at Naini Tal and Darjeeling were also paid for by Government. The proposed work is much too large for Calcutta to bear the whole burden.

Another hospital has been opened in Calcutta. This has been built and endowed by a wealthy Marwari and is intended for Marwaris chiefly, although its benefits will be extended to Hindus generally. It is situated in the heart of the city close to the Marwari quarter. The hospital was formally opened by Lady Curzon yesterday and it is known as the Rai Bhagwan Dass Hospital. An outdoor department has been open for some time. The indoor department consists of one male ward for 20 patients and one female ward for five patients. There will be in addition an accident ward, a lying-in ward, and a contagious diseases ward. There is to be a resident surgeon superintendent and also a lady doctor.

March 8th.

The Plague Epidemic.—The Indian Institute of Science.

A further addition to the already high mortality from plague has been recorded this week. The total deaths from plague throughout India number no less than 23,715, as against 21,789 during the previous week. For the corresponding week of 1901 the deaths were only 7900. Nearly every province shows an increase, but the Punjab is now the chief sufferer and returns no less than 12,544 deaths. The disease has increased in Bombay city, where 888 deaths are recorded; in Calcutta, where the deaths are returned at 462; and in Karachi. The mortality is still very severe in the Bombay districts, from which 4806 deaths are recorded, and it has increased and spread in the province of Bengal, where 1235 deaths have come under notice. In the Madras Presidency there were only 361 deaths, but in the united provinces there were 2187. In Kashmir with 553 deaths, Hyderabad State with 149 deaths, and in the Mysore State with 414 deaths, there is little change.

The proposed institute for scientific research which was known at first as the Tata Institute, having been provided through the liberality of Mr. Tata, a wealthy Parsee in Bombay, is to be formally called the Indian Institute of Science. There are to be three distinct schools, respectively for chemistry, experimental physics, and experimental biology. In the last section will be taken up physiological investigations and of course bacteriological work. The establishment is to consist of three professors and three assistant professors, and later instructors will be appointed from among the successful students. It has now been definitely decided that the site of the institute shall be in Bangalore.

March 13th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Liverpool University.

Two months ago a public meeting was convened by the Lord Mayor to consider the movement for the conversion of University College, Liverpool, into the University of Liverpool. A gratifying evidence of the earnestness with which the movement has been taken up is shown by the advertised subscription list, which amounts to £145,000. Two donors have subscribed £25,000 each. There are three donors of £10,000 each, eight of £5000 each, one of £3000, one of £2000, and 12 of £1000 each. The medical profession has shown a great interest in the new movement, £1050 having already been announced as the subscriptions of eight medical men. During the 21 years of its existence University College, Liverpool, has received gifts in land, buildings, equipment, and endowments amounting to £500,000, exclusive of books in the library, of apparatus in the laboratories, and of the annual income of affiliated schools. The present appeal, as stated in a former issue of THE LANCET, is for an additional capital sum of £330,000, so as to provide for studies that should find a place in any complete system of university education. Additional buildings for the faculty of arts, the extension of the college library, and a hall for examinations and public ceremonies are objects which are specially in view. So far the subscriptions are confined to a small proportion of the citizens. As the object of the movement is to bring the advantages of a university education within the reach of all, it is most desirable that the subscription list should be representative of all classes. Artisans, clerks, and others are specially invited to contribute their mites towards founding the new university.

Lunacy in the West Derby Union.

In his report of his visit to the workhouse infirmary of the West Derby Union Dr. Cooke, visiting Commissioner in Lunacy, stated that he found 109 inmates—58 males and 51 females—classed as of unsound mind, or 24 less than at the visit of his colleague a year ago. This diminution in the number was due to the opening of Winwick Asylum, vacancies having been created thereby at the county asylums. There were vacancies in the imbecile block for 17 men and 22 women, but notwithstanding it was anticipated that the number would be still further reduced. The patients were contented and orderly and he was satisfied with their personal condition and clothing. Some of them were under 14 days' detention orders recovering from the effects of excess in drink, but the majority were chronic cases and he saw but few who needed, or were likely to benefit from, asylum treatment. Great care should be exercised in selecting patients to be sent to the asylums, otherwise those institutions would speedily become filled again and great difficulty would be experienced in finding room for curable and other urgent cases. The register contained only two entries of mechanical restraint; in both instances the jacket was employed. He gathered, however, that troublesome patients were sometimes confined to bed by a sheet tied to the bedstead. This method must be regarded as restraint and entered as such in the register. The Commissioner suggested that some cheap coloured prints should be hung on the walls to brighten the day rooms.

The Country Hospital for Chronic Diseases of Children.

The sum of £18,286 has been subscribed for the building fund of this new hospital. The committee has appeale for £30,000, inclusive of the maintenance fund. The wor of the hospital is carried on at present at the convalescen home at West Kirby, the committee of that institutio having kindly placed 20 beds at the disposal of the committee of the Country Hospital. An anonymous donor o £5000 has made it a condition of his gift that buildin operations are not to be begun until the full amoun required has been obtained. The new hospital will contai 200 cots. 19 patients have been discharged during the yea 1901, the greater number having been inmates for upwards o 12 months. In two cases there was no improvement, whils many were discharged as cured. 22 cases remain unde treatment, the majority of whom are doing well. There wer two deaths during the year.

April 1st.

although that of a thin pale woman of a type extremely convenient for abdominal palpation, was so firm that the examining hand gained little information as to what might be beneath the muscle. Gas and ether were well taken but when ether anæsthesia was fully established there was still firm resistance in the upper part of the left rectus muscle. Operation was decided upon and was performed a few days later. On this occasion, after gas and ether, the patient was brought deeply under the influence of chloroform. The contracted state of the left rectus muscle was uninfluenced. The operation exposed a chronic ulcer on the anterior wall of the stomach with dense adhesion to the under surface of the abdominal wall. It is quite possible that a similar condition of the abdominal wall might occur in a case of chronic appendicitis. In muscular subjects much inconvenience would thus probably be caused, although as a general rule operations on the lower parts of the abdomen, particularly towards the side, are much less interfered with by muscular conditions than those above the umbilicus.

In the case just related there was organic alteration of the muscle, or else a permanent institution of that protective contraction which is so obvious over an acute peritoneal lesion, and which is usually so entirely relieved when the patient is anæsthetised. The contraction is, of course, in the acute cases a reflex phenomenon and is therefore generally abolished, like other reflexes, by deep anæsthesia. Similar instances have lately been described by Sir William Bennett[2] under the name "protective phantoms." When the contraction is met, as in the above instance, naturally the anæsthetist, and still more the surgeon, supposes that if not due to cyanosis or air obstruction it is merely due to too light an anæsthesia. I have satisfied myself that this is not so by pushing chloroform in such a case to the very limit of safety—to a point at which the pupil was dilated to more than three-quarter size and the breathing was beginning to fail—and then inquiring again of the surgeon as to the contracted condition of the muscle. It was as unsatisfactory as before. This state is happily not often seen. If it very seriously inconvenienced the surgeon the only remedy I imagine would be for him to divide the muscle across.

A guide as to the causation and to the irremoveability or not of such contraction may come from noticing the condition of both sides of the abdomen. One side may be quite soft and convenient; the other, which shelters the disease, may be inconveniently firm, as in the gastric case I have related. Of course, the better the muscular development of the patient's abdomen the more inconvenience will these firm recti cause. A case in which they afforded the greatest trouble to the surgeon was that of a young soldier who, since an attack of enteric fever three years previously, had suffered from severe pain in the upper part of the abdomen. In him the contraction of the recti, which were very well developed, was not to be overcome by anæsthetics. Some firm adhesions about the transverse colon and stomach were divided and removed at the operation.

Taking, then, a general survey of the conditions of the abdominal wall which interfere with an operator's convenience, it may be seen that there are some unusual cases in which the anæsthetist cannot remove the difficulty, but that in the great majority of instances he can obtain a perfectly satisfactory condition by maintaining unimpeded breathing, complete absence of cyanosis, and sufficiently deep anæsthesia. These desiderata he obtains by properly selecting his anæsthetic, by giving it freely with a liberal air-supply, by keeping the air-passages free, and by holding the lower jaw well forward. When this is not enough the mouth must be slightly opened and the tongue drawn out. One other point may be mentioned—viz., the element of time. It often happens that only towards the close of an operation is the patient's abdomen in a perfectly satisfactory condition from the surgeon's point of view. It is a good plan, therefore, in abdominal cases to let the anæsthetist get to work at the earliest possible moment—as soon, for instance, as the surgeon begins to get his instruments ready. By such a step a comfortable state may be insured throughout instead of at the close of the operation only the surgeon and anæsthetist witnessing the condition which they had all along been desiring.

URETHRAL HÆMORRHAGE IN GONORRHŒA.

BY J. F. DOBSON, M.S. LOND., F.R.C.S. ENG.,
LATE RESIDENT SURGICAL OFFICER TO THE GENERAL INFIRMARY AT LEEDS.

THE following cases which have come under my care are of considerable interest and are good illustrations of a rare complication of gonorrhœa.

CASE 1.—A man, aged 26 years, attended at the Leeds General Infirmary on Sept. 2nd, 1899. He gave the following history. A month previously he had contracted gonorrhœa; the attack was of moderate severity and a profuse discharge persisted for a fortnight. It then diminished but never completely disappeared. He used an injection of potassium permanganate and also took capsules of santal oil by the mouth. There were no complications and beyond a little pain on micturition and a slight urethral discharge he was perfectly well on the morning of Sept. 2nd. On the evening of that day, after coitus, he immediately had a profuse hæmorrhage from the urethra. I saw him about half an hour afterwards. He had evidently lost a quantity of blood, his shirt and trousers being soaked; bright blood was issuing rapidly from the urethra. The hæmorrhage was arrested with some difficulty by the external application of ice and by injecting into the urethra a weak solution of tincture of hammamelis. He had a recurrence of the bleeding two days afterwards but it was not so profuse and was easily arrested. An injection of a 2 per cent. solution of protargol was ordered but this failed to cure the discharge, and after trying various remedies unsuccessfully I lost sight of him. The treatment adopted in this case was not such as I should now recommend, but at that time I was ignorant of the use of the urethroscope.

CASE 2.—A miner, aged 17 years, attended at the Leeds General Infirmary on Feb. 26th, 1901. He was bleeding profusely from the urethra, so much so that he was brought in an ambulance. He had contracted gonorrhœa six weeks before and had had a urethral discharge ever since. The attack was of but moderate severity and was unattended by complications. He said that the bleeding had commenced when he was working in the pit. He had lost a quantity of blood and a stream of bright blood was proceeding from the meatus. The urethroscope tube was passed and the urethra was inspected. At first nothing could be seen owing to the bleeding, but after mopping the blood away with pieces of wool in holders and inflating the urethra with air it was seen that the hæmorrhage was proceeding from a congested granular-looking patch in the floor of the bulbous urethra. Bright blood was oozing rapidly from this patch. A small fragment of wool dipped in solution of perchloride of iron was applied to the diseased area under the guidance of the electric light. No other patches were discovered. The bleeding ceased at once on the application of the iron and the patient was sent home. There was no return of the hæmorrhage but there was some increase in the amount of discharge which was treated by the use of a 1½ per cent. protargol injection and at intervals by the application of a 10 per cent. solution of protargol to the diseased portion of the urethra through the urethroscope. The discharge rapidly diminished under this treatment and the patient was discharged cured at the end of three weeks. The result of the treatment adopted in this case was most striking and effective.

The next case is of a somewhat different nature to the preceding cases.

CASE 3.—A man, aged 24 years, seen on May 30th, 1901, had had acute gonorrhœa three months previously. The attack had been of considerable severity but there had been no complications. He had a persistent discharge and on several occasions there had been some bleeding from the urethra. This had never been very profuse but was liable to come on after any particular exertion. He had taken various drugs by the mouth and had used a large variety of injections; a metal sound had been passed on two occasions. I saw him a few days after a smart attack of hæmorrhage. A muco-purulent discharge could be expressed from the urethra and this contained gonococci; there was no pain or difficulty in micturition but the meatus was extremely narrow. The meatus was incised, the urethroscope tube was passed, and the urethra was inflated with air. A congested papillary patch was found in the penile urethra, which bled readily on touching it with the probe. The remainder of the anterior urethra was apparently healthy, and there was no evidence of a posterior urethritis. The diseased patch was swabbed with a 20 per cent. solution of protargol through the urethroscope on three occasions at intervals of four or five days, the patient also using a 1½ per cent. injection of protargol night and morning. At the end of three weeks' treatment the discharge had ceased and there was no further hæmorrhage.

I have seen also two other cases of urethral hæmorrhage following gonorrhœa; in both cases the bleeding was profuse and in one it was complicated by retention of urine. These cases were not under my own immediate treatment.

I can find comparatively few references to this complication in medical literature. Erichsen[1] says: "Hæmorrhage from the urethra may occur as the result of chordee and consequent rupture of some blood-vessels of the corpus spongiosum, as the consequence of attempts at passing the catheter, or as a simple oozing from the inflamed mucous membrane." White and Martin[2] mention the occurrence of hæmorrhage at the end of micturition in acute posterior urethritis. "The hæmorrhage may be very free and will pass back into the bladder and the patient will pass it mixed with the urine at the termination of the act." Again,[3] "'Russian clap' is the name applied to gonorrhœa of a hyper-acute type with lymphangitis, obstinate chordee, and free bloody discharge. Bleeding is due to the rupture of the intensely congested vessels of the urethral mucous membrane and both the pus and the semen are tinged with blood." Güterbock[4] describes the occurrence of this complication under the name of black or Russian gonorrhœa. Taylor[5] recommends the localisation of the source of the hæmorrhage by means of the urethroscope. Lydston[6] mentions the bleeding occurring in association with severe chordee. Grünfeld[7] mentions the case of a patient suffering from gleet and passing blood from the urethra who was examined with the urethroscope and a polypus being discovered it was removed by the snare.

It is evident, therefore, that bleeding may occur either in the acute or in the chronic stage of gonorrhœa; in the acute stage with severe chordee or with a posterior urethritis. This is rarely profuse, generally a mere tinging of the discharge, and probably will not call for any special treatment; it would be most unwise to use the urethroscope. In the chronic stage the bleeding may be profuse or slight. Profuse hæmorrhage, as in the first two of my cases, may occur after any extra exertion or after coitus (as in Case 1) in patients who have passed through the acute stage but who still have a discharge from the urethra. The bleeding in the majority of these cases arises from a granular or papillary patch in the anterior urethra; it may be very profuse and may demand immediate treatment. Slight and repeated hæmorrhages may occur in patients suffering from a chronic gleet and may arise from urethral polypi, papillomata, ulcer, or granular patch. Possibly these cases are more common than is generally supposed; a patient may make the statement that he is passing blood in his urine and may conceal the fact that he has a chronic urethral discharge. When a specimen of the urine is examined it will be found to contain blood and the patient may be subjected to much unnecessary and fruitless examination of the bladder and kidneys. If care be taken it is quite easy to ascertain that the hæmorrhage comes from the urethra.

With regard to the treatment of these cases, in the acute stage the hæmorrhage in itself does not call for any special treatment and the case may be managed on ordinary lines. In the chronic stages, when the hæmorrhage is profuse Erichsen[8] recommends the application of ice or the introduction of a large gum-elastic catheter and pressure by means of a bandage to the penis and perineum, probably an exceedingly uncomfortable method of treatment. Rest in bed with elevation of the penis, ice to the perineum, and the use of a weak astringent injection such as sulpho-carbolate of zinc may be successful. Undoubtedly the best results are obtained by the use of the urethroscope; the source of the hæmorrhage may then be detected and the bleeding may be controlled by direct applications under the guidance of the eye to the diseased area. This was the treatment adopted in two of my cases and it was eminently satisfactory. The tube is introduced into the urethra and the blood is removed with fragments of wool in holders; the urethra is then inflated with air and this in itself tends to check the hæmorrhage, the light is applied, and the urethra is inspected. Blood may then be seen issuing from the diseased area. The tube is passed down to this area, the urethra is deflated, and a fragment of wool dipped in a solution of perchloride of iron is applied to the whole of the bleeding surface. Other solutions may be used in preference to the iron, such as tincture of hammamelis, adrenalin, &c.

The effect of this treatment is to increase the amount and purulency of the discharge. This may be controlled by the use of an injection of protargol and the occasional application of a 10 per cent. or a 20 per cent. solution of protargol to the diseased area through the urethroscope tube. If the gleet is due solely to this patch of disease, and not to a posterior urethritis, chronic vesiculitis, or prostatitis, it will be readily cured by this method. If a polypus is, or if papillomata are, the cause of the discharge and hæmorrhage such conditions can be satisfactorily diagnosed and treated only by means of the urethroscope.

I wish to thank Mr. W. H. Brown and Mr. A. W. Mayo Robson, in whose admission wards these cases were seen, for permission to publish them.

REMARKS ON CERTAIN METHODS OF PHYSICAL DIAGNOSIS IN DISEASES OF THE CHEST.

WITH ILLUSTRATIVE CASES.

BY A. G. AULD, M.D. GLASG., M.R.C.P. LOND.,
LATE ASSISTANT PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY,
HONORARY PHYSICIAN TO THE WESTMINSTER GENERAL DISPENSARY.

IN considering the various diseases to which the lungs are subject, a general law as to their distribution is found to operate. It is found that lesions of a tuberculous nature usually attack the apices, whereas most other diseases commonly attack the bases. In reference to the latter it is only necessary to mention such common affections as bronchitis, the various forms of pneumonia, and pleurisy. It is especially necessary to bear this in mind in the case of bronchial affections and the lesions of the pulmonary parenchyma which may complicate them. Just as in tuberculosis the examiner's attention is instinctively, so to speak, directed to the apices, so in non-tuberculous affections it should contrariwise be directed to the bases. No doubt the entire chest ought to be thoroughly examined in every case of suspected disease within the thorax, but it is just in the simpler and commoner conditions—in which the examination is apt to be slipshod—that the bases should be examined with special care. Take, for instance, the case of a troublesome cough remaining after influenza or acute bronchitis. Examination of the anterior part of the chest may be negative and possibly the examiner puts down the cough to some obscure irritation of the bronchi not amenable to auscultation. Now it is very likely that in one or other base, and possibly very low down, an area, which may be quite small, is the seat of numerous bronchitic râles. It is less frequent than is usually supposed that a cough exists the cause of which eludes physical examination.

If, then, the importance of examining the pulmonary bases be so manifest it is necessary that full use be made of all the means which assist in rendering the examination complete. Now, in addition to the usual methods of percussion, auscultation, &c., we have at our disposal others which are both simple and reliable. Two at least of these are applicable in all cases of chest disease, yielding as they always do positive data which materially assist both diagnosis and prognosis. The methods to which I refer are, however, more particularly concerned with the pulmonary bases and so their practical application may shortly be considered in that connexion.

TECHNIQUE OF THE PHYSICAL EXAMINATION.

It is best first of all to determine the condition of the organs immediately underlying the diaphragm, ascertaining the limits of the hepatic dulness and the condition of the stomach and colon as to distension. Any general cause of pressure upwards, as by fluid or tumour, is likewise to be investigated. While this part of the examination is being carried out the patient should be in the recumbent position.

Next as to the examination of the chest itself. It may be said generally that whenever possible the patient should be in the erect position. Lying or sitting up in bed relaxes the abdominal viscera and the muscles of the trunk. This interferes with the free play of the diaphragm and renders the results of percussion less accurate. The percussion note is also impaired in respect of its timbre and mass of tone by the patient's bedding (if confined to bed)

Topography.—It is always well to bear in mind the lines of separation between the lobes of the lungs, and their corresponding position on the surface of the thorax. More particularly it is to be recollected that on the right side the line of division between the upper and middle lobes runs inwards over the fourth rib, or *above* the usual position of the nipple, and that the middle lobe includes all the most anterior portion of lung below this. Also that on the left side the line of demarcation between the lobes runs from some distance outside the nipple sharply inwards and downwards, so as to include in the lower lobe practically all the diaphragmatic surface of that lung.

The bases of the lungs may topographically be divided into three parts or regions. These are the anterior base, the posterior base, and that portion which lies midway between these regions, spoken of as "the lower part of the axilla," the "side," and the "infra-axillary region." As this last-named is a very important area in connexion with physical diagnosis it deserves a shorter and more appropriate designation. It may therefore be termed for present purposes the "axillary base." It may be regarded as bounded in front by a vertical line from the anterior fold of the axilla passing about an inch to one and a half inches outside the nipple line. This may be termed the "anterior axillary line." Its posterior boundary is, perhaps, best ascertained by getting the patient to place his hand on his head. This manœuvre rotates the inferior angle of the scapula into what may be termed the "posterior axillary line." When the patient lies on his back on a hard couch this line, roughly speaking, marks off the visible area of the chest. For practical purposes, therefore, the axillary base may be regarded as the region of the chest below the horizontal nipple line which is bounded by these vertical lines while it is bisected by the mid-axillary line.[1]

Technique.—So much for topography, next as to technique. The inspection of the chest as to formation and the movements of respiration being conducted in the usual way, the patient is placed in position for the observation of Litten's diaphragm phenomenon. He lies on his back on a hard couch, placed exactly opposite a window towards which his feet point. No other light must be allowed to come athwart his body, any other window in the apartment being screened.[2] Standing at the patient's side the examiner will see, when the patient draws a deep breath, a narrow, dark band moving downwards with inspiration and upwards with expiration. This band is caused by a linear depression in the chest wall which corresponds to the line of division between the edge of the lung and the diaphragm. As the diaphragm unrolls off the chest wall, it is closely followed by the thin edge of the lung. *At the moving point of contact* there is a *slight increase* of negative pressure and so the shadow is produced. In the course of many examinations one will seldom fail to observe this phenomenon in a satisfactory manner. Fatness is the *chief obstacle in normal* chests. The *excursion of the* shadow averages from two to four inches according to the respiratory capacity of the individual, and its lower limit is more sharply defined than is its upper. Frequently in thin muscular persons it may be seen over nearly the entire circle of the chest as the patient lies; in other cases it may only be seen at certain points—at the nipple line or the posterior axillary line. Its limits should always be marked off with a pencil. If it be deficient or absent at either base, one suspects a condition which prevents the descent of the lung. Such condition may be pulmonary, pleural, pericardial, or abdominal.

Having noted the range of the shadow the patient is again placed in the erect position and the chest is palpated. The only remark which may be made in this connexion is that it is well to test the vocal fremitus with the *edge* of the hand. The outer edge of the hand is applied transversely and is moved down successively over each rib and intercostal space. The fremitus is thus noted over smaller areas than could be possible by the application of the entire hand. This procedure will sometimes be found to supply information of very great value.

Percussion next claims attention and it is here intended to consider a special application of it. We have seen that the downward expansion of the lungs may usually be determined by the diaphragm shadow. The same information is afforded by percussion. If the inferior border of the pulmonary resonance be found on quiet expiration and marked off with a pencil from the liver dulness, a deep inspiration will cause an extension of resonance downwards to percussion, according to the *extensibility of the lung border. This distance* should correspond pretty accurately with that yielded by the shadow. There is thus a double test available for the pulmonary extension downwards. And it is well that it is so, for in many cases of disease of the base in which the *pulmonary excursion is too small to be perceived* by the shadow it may be ascertained by percussion. I think that this method of determining the limits of the pulmonary expansion, whether at the bases or over the cardiac dulness, may be termed "limitary percussion."

The greatest downward extension of the lung takes place at the axillary base and it is here that limitary percussion should usually be made. On the right side the liver dulness is our guide. The patient, standing upright, should be directed to place his right hand on his head. He should not, however, lean to the opposite side, as this position tends to render the pulmonary resonance at the edge of the lung more diffuse. The line of demarcation between the resonant and dull areas in the resting state of the lung being marked with a pencil, the extension of the resonance downwards with a deep inspiration is determined, and in like manner the recession of resonance upwards above the line is ascertained during a deep expiration. On the left side the conditions are different. Here the stomach tympany takes the place of the liver dulness. But in the *spleen* we have a body which serves as a satisfactory indicator. It is necessary first of all *to percuss out the spleen. If the splenic* dulness is absent it is likely that either the stomach or the colon or both of these viscera are distended. But there is another warning to be given. In one or two cases I have found that whereas in the recumbent position (i.e., the patient lying on his right side) the splenic dulness was replaced by a stomach note, it nevertheless became perfectly apparent on the patient's assuming the upright position. This somewhat rare phenomenon is one which does not appear to be described in any of our text-books. In the resting state, the edge of the lung usually overlaps the upper limits of the spleen. The examination is conducted as on the right side, the patient placing his left hand on his head. During a deep inspiration the lung border descends over the organ and provided this body be of the usual size, the results of limitary percussion are quite satisfactory. It is evident that this method of percussion *is not applicable unless there* is resonant lung over some part of the extreme base.

Before leaving the subject of percussion, reference must be made to the direct or immediate variety—a factor in diagnosis which has undeservedly fallen into disuse. It *may* be practised with the tips of the first three fingers gathered into a point with the thumb in apposition to the first finger or by using the middle finger alone. The latter method is generally preferable. The stroke should be *fairly* sharp and should be made over a rib. I am inclined *to* think that this mode of percussing sometimes gives more accurate information than mediate percussion. It requires some practice to be properly appreciated but it will yield in almost all cases quite as reliable results as the mediate variety, while, as stated, in not a few cases it is the more sensitive test, especially as regards the sense of resistance.

The remaining method of diagnosis which shall here be considered is applicable only to a limited number of cases. It demands, even more than those already described, the intelligent coöperation of the patient and may be defined as *that of "forced* breathing." In this the patient is requested to take a number of deep breaths in succession. Sometimes a dozen may suffice, but in other cases 30 or 40 may be necessary, in the course of which a short interval of rest may be permitted. When a lung, or at least its basal portion, has undergone a certain degree of compression or collapse, forcible breathing will sometimes alter the condition of affairs in a very remarkable manner. The collapse affecting the base which is induced by bronchitis in young persons may temporarily be made to disappear, dulness and feeble breathing being replaced by resonance and free breathing. It is necessary, however, that the acute symptoms shall have passed off, that the bronchial tubes are permeable to air, and that the collapse is not too extensive or deep. The same transformation may be produced to a greater or less extent in a lung which has undergone compression from pleuritic effusion. It is obvious that this test is only applicable to patients of a certain age, while the results obtained are only temporary. Nevertheless, the information yielded is extremely valuable.

---

[1] Clinically, the base of the lung refers to all the pulmonary region below the horizontal plane at the apex of the diaphragm.

[2] *A good artificial light will suffice in the absence of daylight*

Such, then, are the particular diagnostic criteria to which I have wished to refer in connexion with the investigation of morbid conditions of the lungs and more particularly of their bases. It now remains to illustrate their application in a few cases of disease affecting these regions. Three cases have been selected in which the morbid signs were almost exclusively confined to one or other base, thus rendering unnecessary any specific allusion to the condition of the organs generally.

ILLUSTRATIVE CASES.

CASE 1.—The patient, a man, aged 47 years, complained of cough lasting for three weeks with considerable expectoration. On the left side the diaphragm excursion was two inches, percussion resonance was good, and limitary percussion gave an extension of the pulmonary border downwards two and a half inches at the axillary base Auscultation revealed a few sonorous and mucous rhonchi accompanying the breath sounds which were otherwise normal. On the right side the diaphragm shadow was absent, the percussion note was impaired from the seventh intercostal space behind to the extreme base, and there was no extension to limitary percussion. Vocal fremitus was more marked over this area and vocal resonance was slightly increased also. The breath sounds were faintly heard and were of bronchial character, the latter part of inspiration being obscured by numerous small mucous râles of a rather crackling quality. A few such râles were also present on expiration. On deep breathing the râles were much increased at the termination of inspiration. They were not affected by cough. After a week there was still no movement of the shadow but at the axillary base percussion gave an extension downwards of a finger-breadth on deep inspiration. Otherwise the signs over the base had undergone but little alteration. There were still some impairment of resonance and numerous mucous râles. After the lapse of another week the shadow was seen to be moving for about an inch on the right side and percussion at the axillary base gave a downward extension of one and a half inches. The dulness had practically disappeared to mediate percussion, but direct percussion yielded a distinct sense of resistance as compared with the left base. The vocal fremitus and resonance were but slightly different from those on the left side; the breathing was broncho-vesicular and the râles had become much softer. Five weeks elapsed ere there was another opportunity of seeing this patient. On listening over the right base a number of subcrepitant râles were heard at the end of deep inspiration. After eight or nine deep breaths these all disappeared with the exception of a few in a narrow zone at the extreme base. The shadow excursion was over two inches (the same as on the left side) and the limitary percussion coincided. Vesicular breathing was restored and the lung was practically normal.

It is sometimes well to listen over the bases before carrying out inspection and percussion, because in the course of the latter the deep breathing which is necessitated may dispel any atelectatic crepitation. If we wish to know whether atelectatic crepitation exists this precaution is necessary.

There can be little doubt that in this case there was some broncho-pneumonia of the right base—a condition not so rare in adults as some imagine. Yet many authors have noted that in adults bronchitis of the base is occasionally characterised by an impaired percussion note and more or less bronchial breathing. In these there is generally some collapse as well. When the disease is at its height this collapse cannot be overcome by forced breathing. It is only when the lung is on the road to recovery and when the obstructed bronchi are more or less relieved that the air can be forced through so as temporarily to inflate the lung. As regards the physical examination it is interesting to note that the earliest reliable sign of improvement consisted in the slight extension downwards revealed by percussion. This occurrence warranted a favourable prognosis. It indicated that the lung had begun to recover; it also indicated that there were no pleuritic adhesions of much extent at the base.

It may be pointed out here that a small circumscribed consolidation at the base does not abolish the shadow. The non-appearance of the shadow (provided it be present on the opposite side) points to an extensive distribution of the morbid process.

CASE 2.—The patient, a female, aged 20 years, had suffered from cough for two months which had become worse latterly. There was much mucous expectoration. On the right side the diaphragm shadow was well seen for about one and a half inches. Vocal fremitus was unsatisfactory (the patient had a very weak voice). Percussion was normal. Limitary percussion gave a pulmonary expansion of two inches at the axillary base. Auscultation revealed some piping and sonorous rhonchi. On the left side the diaphragm shadow was absent and vocal fremitus was doubtfully felt. The percussion note was dull from near the angle of the scapula downwards over the lower lobe and extending forwards as far as the mid-axillary line. Limitary percussion impracticable. On auscultating in the upper part of the lower lobe the breathing was harsh but vesicular and there were a few mucous râles present. In the lower part of this lobe the breath sounds were very feeble and were nearly obscured by mucous râles. The râles accurately followed the line of division between the upper and lower lobes round to the nipple line and then to the bottom of the lung. In the lower part of the posterior base the râles were distinctly ringing in character. These signs remained practically unaltered for three weeks and naturally they gave rise to a suspicion of tuberculosis. There was very abundant expectoration but it was purely mucous. Examination during the fourth week revealed, however, some indications of improvement. There were a slight extension to percussion and a suspicion of a shadow movement. The dulness was also considerably diminished but the râles were practically unaltered nor were they much influenced by cough. The patient continued under treatment but it was six weeks before I saw her again. She was then greatly better. After a few deep breaths the shadow moved quite two inches on the left side, equal, indeed, to that on the right, and the dulness had disappeared. There was still a mucous râle audible at the end of a deep inspiration and a few sonorous rhonchi were scattered over the chest.

The next, and the last, case illustrates more particularly the effects of forced breathing on a lung which had undergone partial collapse due to a long-standing lesion of the base. The organ had been gradually recovering but the elasticity of the tissues had evidently been much impaired both by the disease and by prolonged disuse.

CASE 3.—The patient was a girl, aged 12 years. According to the mother's statement she had been suffering from the effects of "inflammation of the lungs" since she was eight years of age. She was very well nourished and well grown, had no appearance of tuberculosis, and the sputum, which was expectorated in fair quantity, was free from the tubercle bacillus. The entire right lung and the anterior part of the left lung were perfectly sound. Inspection showed the left base to be somewhat retracted and to expand but little on deep inspiration. The shadow was also absent over this side, but neither could it be seen on the right side. No vocal fremitus could be obtained over the left base but it was very faint in every region. The percussion note was quite dull below the eighth rib behind, the dulness shading off somewhat towards the mid-axillary line, but nevertheless it was apparent to a certain degree also over the axillary base. Auscultation revealed numerous râles of a crackling character over the dull area which were especially marked on deep breathing. Towards the extreme base the auscultatory signs were almost negative. The vocal resonance, so far as one could judge, was diminished This girl continued for months without any alteration in the physical signs and enjoyed good health. Her only symptoms were cough with considerable expectoration. One day last summer she presented herself, much changed for the better. The retraction of the left base was barely visible and there was some expansion outwards on deep breathing. No shadow movement was visible. The dulness had distinctly diminished except at the very bottom of the lung; the breathing, though feeble, was evidently becoming re-established and the râles were chiefly confined to the end of inspiration. The patient was now got to practise forced breathing. She continued to excite as deep respirations as she could, and on listening over the affected base during this process one heard the air during the first part of inspiration as if struggling with some obstacle, passing slowly and accompanied by a few râles. It then broke into a "puff," terminating with a number of crepitations. The latter part of expiration was also performed in a halting manner but without the râles. It was bronchial in character. After the patient had continued the deep breathing for several minutes it was found that the râles had disappeared, the breath sounds had become sufficiently loud and free, and the percussion tone was perfectly resonant. Moreover, the edge of the lung descended two inches to percussion—a distance equal to that obtained on the right side. Owing to the stoutness of the patient no shadow was visible on either side.

I have seen other cases in young persons wherein collapse, if not too extensive or deep-seated, could be overcome by this method. Forced breathing will also inflate the compressed lung to a certain extent during the existence of a pleuritic effusion or after its absorption. In the case of tardy recovery of the pulmonary elasticity after broncho-pneumonia or pleurisy it is probable that forced breathing should form part of the treatment and be performed as a daily exercise.

Not having seen the last patient from the beginning of her illness, I am unable to say what lesions she may not have had. But when she first presented herself the condition of the extreme posterior base of the left lung was somewhat difficult to diagnose—as the signs of collapse when uniformly affecting this zone are very similar to those of a small effusion or of thickened pleural membranes. As it turned out she was suffering from chronic or rather subacute broncho-pneumonia with pretty extensive collapse. If pleurisy had existed for so long a time it is very unlikely that it would have left no adhesions or thickening at the extreme base. The absence of such is proved by the extension downwards which was demonstrated by limitary percussion.

Perhaps the notes of these cases, out of a considerable number which I have collected, may suffice to indicate the importance of utilising the various procedures to which reference has been made.

NOTE ON A

CASE OF ARTHRITIS ACCOMPANYING OPHTHALMIA NEONATORUM.[1]

BY C. O. HAWTHORNE, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL;
ASSISTANT PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL
AND TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

FOR a recognition of the fact that the purulent ophthalmia of newly-born infants may be associated with joint complications analogous to those which not infrequently attend urethritis we are indebted to Mr. R. Clement Lucas.[2] His first observation, made so far back as 1885, was perhaps not unnaturally subjected to the ordeal of a somewhat incredulous criticism. From this, however, it emerged successfully and the suggestions that his case might have been one of epiphysitis or of syphilitic synovitis were successfully met by clinical arguments that can hardly be gainsaid. The lapse of time has provided further evidence. This is by no means abundant so far as volume is concerned, but it is supplied by a number of independent observers and contains elements which raise it to the level of established proof. To judge from systematic works dealing with the subject of ophthalmia neonatorum it would appear that Mr. Lucas's original observation hardly attracted the attention which it deserved, though for this some excuse may perhaps be found in the fact that, with one exception, recorded by Mr. R. G. Fendick,[3] also in 1885, no parallel case was recorded in Great Britain during a period of 13 years. And when Mr Lucas in 1899 introduced the subject to the Royal Medical and Chirurgical Society a search through European medical literature had resulted in the discovery of only 23 cases. Writers on gonorrhoeal rheumatism subsequently to Mr. Lucas's case, however, began to recognise the occasional occurrence of joint complications in ophthalmia neonatorum and the association was mentioned by Dr. Archibald E. Garrod[4] in 1890 and by Dr. J. Mitchell Bruce[5] in 1894. More recently Mr. Sydney Stephenson[6] has given some interesting particulars of the character of the joint affections, and Dr. L. Vernon-Jones[7] has also drawn attention to them. Yet, from what has been stated above the cases are anything but numerous, and so it seems desirable that examples of the condition should be put upon record, more particularly as in some instances the subacute character of the inflammation and its temporary duration may cause it to be overlooked.

The example now to be reported can only claim the interest that it confirms the results of the earlier observations, more especially as regards the possibly quiet nature of the arthritis and the prompt and thorough restoration of the efficiency of the affected joints. The diagnosis in this individual case was not confirmed by bacteriological examination, though this has been accomplished in other instances in reference both to the conjunctival discharge and the synovial effusion. But as we have medical warrant that the father of the patient had gonorrhoea two months before the child was born, that the mother was subsequently affected, and that the child began to suffer from purulent ophthalmia when two days old the diagnosis is not open to doubt.

The earlier particulars of the case, for which I am indebted to Dr. John Clarke, are as follows. The affection of the eyes commenced two days after birth and an abundant purulent discharge continued for fully three weeks. When the child was a fortnight old the right shoulder-joint became considerably, and the right wrist slightly, swollen without apparently causing the child much discomfort and the swelling subsided in the course of a fortnight without any very active treatment. When the child came under my observation he was six weeks old. There was still a slight amount of muco-purulent discharge from the conjunctivæ and the right cornea presented a small abrasion from which a diffuse haze spread through the corneal substance. It may perhaps be conjectured that here is to be found the explanation of a further outbreak of joint inflammation. For while the joints which were first attacked—that is, the right shoulder and wrist—had completely regained their normal characters the left elbow-joint was much enlarged and the swelling extended down the radial side of the forearm for a considerable distance, giving here a sensation of deep fluctuation, as though the sheaths of the muscles were involved. The skin was not reddened and though the child objected to manipulation of the joint he appeared otherwise to be free from pain and his general nutrition was entirely satisfactory. It was decided to fix the limb and to continue the local treatment of the ophthalmia and under these measures the patient made a rapid recovery, so that in from two to three weeks the elbow-joint and forearm had regained in every respect their normal characters.

Attention may first be drawn to the subacute character of the successive attacks of arthritis. Almost from the outset of his observations Mr. Clement Lucas recognised that two varieties of arthritis associated with ophthalmia neonatorum occurred—viz., (1) a very acute form with features suggesting a tendency to suppuration and (2) a milder form accompanied by a great deal of effusion and pain on movement but with little or no surface redness. The present case adapts itself exactly to this latter form. A second feature worthy of note is the extension of the swelling beyond the limits of the joint cavity. This is, of course, a well-recognised event in many cases of arthritis of urethral origin and Mr. Sydney Stephenson has drawn attention to "effusion into the sheaths of the tendons" in the neighbourhood of the affected joints in cases where the primary gonococcal inflammation involves the conjunctiva. The joints most commonly affected would appear to be the knees and the wrists, but in the present case the knees escaped altogether and the stress of the disease fell on the right shoulder and left elbow. It may be added that no history of injury could be obtained and there was no evidence of syphilis in either the child or the parents. Lastly, the promptness and completeness of the restoration of the joints to normal may be noted. This is in harmony with other records and supports and justifies the presentation of a favourable prognosis in these cases. It is a feature of the condition in pleasing contrast to the obstinate and often prolonged evil effects which so frequently attend the usual form of gonorrhœal arthritis. The explanation is doubtless to be found in the ease and readiness with which a purulent ophthalmia can be successfully treated as compared with the difficulty of bringing to a close the opportunities for absorption of a purulent discharge offered by the urethra and its related glandular recesses. The difference between the course of the arthritis in a case of gonorrhœa on the one hand and in ophthalmia neonatorum on the other lends emphasis to the statement that the checking of the urethral discharge is the first claim in a case of gonorrhœal arthritis. It can hardly be supposed that the delicate tissues of the child's joints are more resistant to the gonococcal poison than are those of the adolescent or adult, and the explanation of the contrasted joint complications must therefore be found in the readiness with which the supply of poison is removed in the one case and the difficulty with which it is checked in the other.

THE ADVISABILITY OF PRELIMINARY TRACHEOTOMY AND LIGATURE OF THE EXTERNAL CAROTID IN SEVERE OPERATIONS ABOUT THE FACE.

BY CHARLES R. KEYSER, F.R.C.S. ENG.,
SURGICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

PRELIMINARY tracheotomy and ligature of the external carotid artery are indicated in excision of the upper jaw, excision of the lower jaw, and removal of the tongue in some cases. In the latter, where a small portion only has to be removed and that portion is at or about the tip of the organ, this method is unnecessary.

In advocating what at first appears to be a somewhat severe measure I am aware that there are many who can point to a large number of cases in which the operation has been most successfully accomplished without the preliminary tracheotomy and ligature of the external carotid artery and in which the patient recovered without any untoward symptoms. But I maintain that in the majority of instances in which the operation, especially of removal of the upper or lower jaw, is required it is practically impossible to tell beforehand what the difficulties will be. To some extent, no doubt, it may be surmised that in one direction—viz., hæmorrhage—there will or will not be much danger; for example, in dealing with a rapidly growing exceedingly vascular sarcoma, hæmorrhage is expected and arrangements are made accordingly, but it is impossible to foretell in any given case whether the jaw can be removed with ease and comfort to those chiefly concerned, these being the patient, the operator, and the anæsthetist.

The main reasons for advocating the triple operation are as follows. The almost complete absence of bleeding after the external carotid has been ligatured. Besides the danger to the patient from loss of blood, which in many cases can be efficiently controlled without tying the main vessel, hæmorrhage obscures the view of the affected parts and renders it more likely that some portion of the growth or diseased tissue may be left behind. The operator is much more at his ease and need not be in a hurry. This is especially an advantage in removal of the superior maxilla for malignant disease. All surgeons must have seen cases where in this operation everything goes quite satisfactorily up to the point of twisting out the bone with lion forceps and giving the last few cuts with the knife which sever the remaining tissues which still hold the bone in place. What so often happens at this point? In the large majority of instances the bone and growth crumple up under the pressure of the forceps and are torn out in pieces, soft masses of growth and hard spicules of bone being forced in all directions, often into the patient's pharynx or even into the larynx, and all is for the moment flurry and excitement, the surgeon endeavouring to get away the bone and growth and the anæsthetist sponging out the pharynx to enable respiration to be carried on. Even if these conditions are absent the last few strokes of the scalpel often divide some large vessel, such as the internal maxillary artery, and the field of operation is flooded with blood. With the external carotid ligatured and a tracheotomy tube in place, the pharynx being plugged with a sponge, none of these difficulties occur and the operator and the anæsthetist can proceed with deliberation and ease. Apart from a perhaps slight immediate danger of hæmorrhage there is another point: no blood enters the larynx and air-passages.

In a certain number of cases, no doubt much smaller now than formerly, broncho-pneumonia supervenes in a few days after operations such as excision of the tongue or jaw. This is nearly always septic in character and many patients have lost their lives from this cause when the operation has been quite successful in all other respects. I believe that the cause of this lung-trouble is almost invariably the result of putrefaction taking place in blood or blood-clot which has entered the air-passages at the time of operation. It is often stated that this complication is caused by the air which is inhaled passing over the wound and so carrying some virus to the lungs but the treatment of the cut surface nowadays is such that this cannot be reckoned as having much influence in the production of broncho-pneumonia. On this point I have quite recently seen two cases of partial excision of the tongue which bear on the question. Both were cases of epithelioma of the tongue; in one the patient was comparatively young and strong, the growth was of short duration, the tongue was not adherent, and there were no enlarged glands in the neck. In the other case a man was older and more feeble, the tongue was slightly adherent, and there were epitheliomatous glands in the neck. Both were operated upon on the same day by a well-known surgeon whose skill is beyond question. In the first case the growth was excised in the ordinary way by Whitehead's method. In the second case the glands in the neck were first removed and the external carotid was ligatured before removing the tongue. In this case the patient soon recovered and is now quite convalescent. The other, in whom the carotid was not tied, developed an irregular temperature, cough, and shortness of breath, and is still exceedingly ill. Signs of fluid in the chest appeared and a large horribly foul empyema was opened and drained. It had apparently been caused by an abscess in the lung and surgical emphysema developed all over the affected side of the chest. Although in the case given tracheotomy was not performed, the absence of all hæmorrhage and, in consequence, of all septic changes occurring in the air-passages, prevented any complication of the lung. I may also mention that the two patients are not only in the same ward and looked after by the same nurses, &c., but are in adjoining beds, so that the possibility of any external cause for the complication of the lung is extremely improbable.

It is of great importance to ligature the external and not the common carotid artery, as if the latter proceeding is done the hæmorrhage is very inefficiently controlled owing to the exceedingly free anastomosis through the circle of Willis and there is some danger of cerebral symptoms appearing subsequently. The most convenient position for the ligature is between the superior thyroid and lingual branches and in this situation the operation is not of great difficulty. Although, as mentioned above, there is not, as a rule, much danger to life from hæmorrhage if the carotid is not ligatured, yet within the last two years I have seen two fatal cases, one in which half of the tongue was removed for a papilloma and another in which excision of the upper jaw for sarcoma was performed.

There is no necessity to use a special tube or tampon for the trachea as an ordinary tube answers every purpose if at the same time the pharynx is plugged with a good-sized sponge. The following cases, which Mr. Herbert W. Allingham has kindly allowed me to publish, illustrate the kind of disease in which this method of operating is of use. The first four have already been published[1] but the remainder have not yet been recorded.

CASE 1.—The patient, aged 48 years, was suffering from epithelioma of the posterior part of the tongue, involving the anterior pillar of the fauces and the floor of the mouth. The submaxillary and the vertical chain of cervical glands were also infected. The left half of the tongue and all the glands were removed.

---

[1] Practitioner, May, 1899, p. 572.

CASE 2.—The patient, aged 41 years, was suffering from a malignant ulcer of the right side of the tongue, involving the floor of the mouth, the submaxillary and the cervical glands. The right half of the tongue and all the glands were removed.

CASE 3.—The patient, aged 67 years, was suffering from a sloughing epitheliomatous growth involving the left side of the lower jaw. The latter was excised.

CASE 4.—The patient, aged 33 years, presented an enlargement of the superior maxilla with bulging of the palate downwards, and extension upwards on the face involving the skin and causing closure of the eyelids. The upper jaw was excised.

CASE 5.—The patient, aged 60 years, had extensive epithelioma of the anterior half of the tongue. This was removed.

CASE 6.—The patient, aged 48 years, was suffering from very extensive sarcomatous growth arising from the antrum and extending through the floor of the orbit and also into the ethmoid. The tumour was very soft and friable. The upper jaw was removed.

CASE 7.—The patient, aged 44 years, had very extensive carcinoma of the antrum which involved the nose, the pharynx, the lower jaw, and the tissues behind the internal pterygoid muscle. The upper jaw and all the growth were removed.

CASE 8.—This case was one of malignant disease of the lower jaw; this was excised.

In all these cases the triple operation was performed; there was practically no hæmorrhage or any cause for anxiety and all the patients made an excellent and rapid recovery. The tracheotomy tube may be removed on the day following the operation and there is never any trouble arising from the wound in the trachea. I feel sure that if these preliminary steps are taken in all such cases where extensive surgical proceedings are necessary, the operation of either excision of the upper or lower jaw will cease to be regarded as one of great difficulty or danger.

St. George's Hospital.

NOTE ON TWO CASES OF "ULCERATED SORE-THROAT."

BY EDWARD C. BOUSFIELD, L.R.C.P. LOND., M.R.C.S. ENG.,

BACTERIOLOGIST FOR THE BOROUGH OF CAMBERWELL.

IT will be thought incredible in 20 years' time that with means of rapid and accurate diagnosis at hand and with a remedy of proved efficacy available patients should have been allowed to incur serious and often fatal risks for want of the application of the one and the employment of the other. At the present moment, unfortunately, daily experience shows that a large number of medical men allow themselves to be bound by the old traditions, handed down from days when bacteriology was unknown, as regards both the diagnosis and treatment of throat affections of a more or less doubtful character.

The two cases with which I propose to deal have both occurred within my own immediate family circle and the results have been such as I have described. In the first, a slight attack, my request to be allowed to have a swab sent to me for examination was refused, and even when fluid began to return through the nostrils and speech was affected the practitioner in attendance strenuously denied that the attack had been one of diphtheria and said that he had seen paralysis follow tonsillitis. The patient has since suffered from paralysis of nearly all the chief motor centres, one after another, and is now only slowly and partially recovering. In the other case, unfortunately, the results have been far more serious. The patient, taken ill with an attack in which there was on the second day a "slough" upon one tonsil, which repeated itself upon the other and was followed by a similar patch on the uvula, succumbed on the fifth day to suffocation caused by extension of the disease to the larynx and trachea. In this case, but for the positive assurance up to the end of the fourth day of the practitioner in attendance that the case was not one of diphtheria, the parents would not only have permitted but insisted upon the employment of antitoxin and bacteriological examination.

It will be seen that the net result of the "ulcerated throat" heresy in these two cases has been disastrous and the practitioners in attendance have lost the confidence of the parents in each case because they relied absolutely upon their own unaided, and therefore necessarily uncertain, diagnosis, when the latter might have been made certain, or rather corrected, within a few hours.

My main object in drawing attention to these two cases is to repudiate in the strongest possible terms the idea that "ulceration of the throat"—i.e., the presence of a "slough" upon the tonsils or pharynx—can be due to other than one of two causes—namely, syphilis and diphtheria. Follicular tonsillitis, in which the follicles become blocked with a white secretion as hard as cartilage in many cases and containing usually only diplococci, has nothing in common with either of the two just mentioned. In this case the secretion can be removed and the surface of the tonsil is unaffected by the act. In quinsy I have never seen a membrane of any kind upon the surface of the tonsil, and scarlet fever does not enter into the question

I am well aware that in some cases which are genuinely diphtheritic the specific bacilli are not found. The explanation of this fact is twofold. First, in slight cases their number may be but small and it is necessary after about nine hours' growth to distribute the small number of minute colonies present over the surface of the medium—that is, to re-sow or to plant out the organisms in order to demonstrate their presence. The second point is that the material from which the culture is made may not have been properly taken. I attach the greatest possible importance to thorough wetting of the swab. The diphtheria bacillus does not possess a very high degree of resisting power, and when absorbed in addition into the interstices of a dry swab, possibly in very small numbers, the transference to the culture medium may be fruitless. I contend, however, that with a swab properly taken and sufficient care in the examination the cases of "ulcerated throat" in which the bacillus of diphtheria will not be found are infinitesimal in number. It may be worth while to add that since the culture medium is highly selective the use of ordinary water for wetting the swab is quite unobjectionable.

It may also be added with reference to treatment that there is no justification in a doubtful case for postponing the use of antitoxin. In a previous communication I stated that the use of antitoxin was as harmless as the injection of water. To this statement the Editors of THE LANCET rightly took exception. I admit, and apologise for, the error, as I should have stated that whilst water may conceivably contain germs of disease antitoxin properly prepared is a sterile fluid of unirritating qualities and therefore less likely to be injurious than water. Personally, I have never heard an objection raised by a patient or by the friends of a patient to the use of the remedy. Of course, if the medical attendant speaks doubtfully of the remedy and refers to the pain of the injection he has no one to thank but himself if the lead so given is followed. My experience is that the dread of diphtheria in the popular mind is rightly so great that the assurance of cure, or of a fair prospect of it, is eagerly welcomed, and that there is not the least difficulty in inducing persons exposed to infection to submit to prophylactic injections. At the moment of writing, having yesterday received a full prophylactic dose, I am absolutely unable by my sensations to locate the seat of injection, and the operation itself is one which I have frequently performed even upon young children with scarcely a whimper on the part of the subject.

The importance of the matter must be my apology for the length of this communication. Five years' work as a municipal bacteriologist has made me fairly well acquainted with the position of my brethren on this subject, and it is in the hope that a few more converts may be secured that I have been tempted to publish my own most regrettable experiences.

Old Kent-road, S.E.

PLYMOUTH BOROUGH LUNATIC ASYLUM, BLACKADON.—The report of the Plymouth Borough Lunatic Asylum for 1901, which has just been issued, states that there were 275 patients in the institution at the beginning of 1901 and 54 cases were admitted during the year. 19 deaths occurred and 28 cases were discharged recovered, four were relieved, and 10 were not improved. The cost of maintaining patients was 10s. 6d. per week per head. The committee reported that the sanction of the Local Government Board has been given to a loan of £40,000 for the extension of the asylum buildings and the work is to be shortly commenced.

RADICAL CURE OF INGUINAL HERNIA.

By JOHN O'CONOR, M.A., M.D. DUB.,
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AYRES.

So much has already been written on the subject of the radical cure of inguinal hernia that I feel a little diffidence in publishing some conclusions derived from 350 operations, 140 of which were performed by Halsted's, 120 by Kocher's, and 90 by Bassini's and other methods. As elsewhere stated[1] I had to abandon Halsted's operation owing to the too frequent supervention of orchitis, with consequent atrophy of the testis, which I attributed in part to removal of veins irrespective of varicocele—vessels which presumably have some functional reason for existence. I considered, also, transplantation of the cord from its normal conduit to be very questionable surgery, in that no one can determine the amount of pressure which may arise from subsequent cicatricial contraction, not to mention the immediate possibility of backflow from injudicious suturing. The cord naturally passes out of the abdomen through the internal ring, which is anatomically so constructed that no undue pressure can be exercised on its contents, yet we find ourselves performing operations by the hundred in which the capacity of outlet is left to speculation, for contractile living tissue is beyond the pale of mathematical calculation. Recently it has been reported that Professor Halsted has abandoned transplantation of the cord. If this should be so I think that he has made a move in the right direction, and he might further improve his operation by omitting the removal of veins which in many instances leads to fatty degeneration and ultimately to disappearance of the testicle.

These remarks as to tampering with the position of the cord apply equally to Bassini's method, in which it is placed between the oblique. This operation has a further important disadvantage in that an intermuscular space is created in which the cord rests, which obviously renders the procedure inferior to that of Halsted, who brings all the muscles into close juxtaposition and also affords a convenient site for the collection of serum which, taken in conjunction with buried sutures, only requires the ubiquitous coccus to create a sore which may weep for months or years. We are informed by some that buried sutures never cause any trouble, and by others, equally dexterous and aseptic, that they never use them if it can possibly be avoided as their experience is just the reverse. After a personal experience of over 1000 abdominal operations I confess that I am most sceptical as to the tranquillity of buried unabsorbable sutures, particularly silk, in the abdominal wall, and I think that the indiscriminate manner in which the latter is used in many hospitals is extremely reprehensible. Still, every surgeon must of necessity occasionally employ them, and a rule might with advantage be instituted never to bury an unabsorbable stitch in a submuscular cavity where serum and blood are prone to collect and to corrupt.

Bassini, Halsted, and Macewen have the same object in view—the approximation of the deeper muscles—and all credit must be given to their originality in establishing a practical and logical basis for any reasonable method of radical cure. Notwithstanding this Kocher's operation has many partisans, which I think must be attributed to its simplicity, yet I cannot admit that his method of fixing the stump of the sac to the abdominal wall, with or without inversion, can materially influence the cure or the probability of recurrence. As one's experience grows one is forced to place little reliance on peritoneal adhesions. At best their function is very temporary in plastic surgery; reference to the illustrations in the chapter on Hysteropexy in Howard Kelly's "Gynecology" will confirm fully this statement. Again, I have often puzzled over the *rationale* of his method of reefing the aponeurosis over the inguinal canal which is done by infolding. It stands to reason that the infolded external oblique must act as a buffer by which the deeper structures are prevented from approximating when the sutures are drawn taut. Notwithstanding these objections Kocher's operation has yielded me as good results as the others, with about 6 per cent. (reported) of recurrences, with decidedly less orchitis, and with a further advantage—no splitting up of structures which surgery cannot replace. No amount of cicatricial plastering can ever imitate the normal formation of the part, and as Professor Kocher truly remarks about his operation, if recurrence does take place the patient is no worse off than before. The same cannot be said of a Bassini, a Halsted, or a Macewen method, for it has fallen to my lot to undertake secondary operations in cases which had been treated by the latter methods, and in each instance I encountered an attenuated cicatricial jumble which not only rendered the execution of any operation difficult but taxed one's resources to the utmost to find material with which to build up even a pretence of a fortification. In other words, if recurrence follows division of the internal or external oblique the last state is emphatically worse than the first.

Having had ample opportunity of studying the merits of the various structures concerned with inguinal hernia (I wish here to express my gratitude to Professor D. J. Cunningham and Professor Moorhead of Dublin University for recently furthering my knowledge by demonstration on the dead subject), I have come to the conclusion that the keystone to any radical cure is the approximation of the conjoined tendon to the lower shelf of Poupart's ligament. The latter, by the way, is well known to students of anatomy but inferiorly comprehended by many surgeons who imagine themselves capable of performing an orthodox Bassini operation. Probably it would be expedient to dispense with the term "lower shelf" altogether and to stick to the anatomical one, "Gimbernat's ligament," which it may be well to remember *is continuous along its inferior margin* with some fibres of Cooper's ligament.

I have practised the following operation in 20 cases and so far with satisfactory results. A four-inch incision is made over the line of the inguinal canal, the sac is isolated from the cord, it is opened and its interior is carefully inspected, and it is palpated well into the abdominal cavity. (Some years ago, by the way, I had the misfortune to ligate and to excise an inch of cæcum which the above precaution would have obviated.) Next, my assistant draws the sac forcibly downwards, and while retaining my left index finger within the sac near to the internal ring in order to prevent intestine or omentum getting caught, I transfix and ligate with catgut and cut away the distal portion. Before complete separation takes place a pressure forceps is applied to its proximal end, in order that a final inspection may be made before it is allowed to fly back into the abdomen, for a chase after a bleeding point in a retreating stump is not pleasant. The conjoined tendon and Gimbernat's ligament are next thoroughly differentiated from the surrounding parts and with the left index finger introduced into the canal to act as a guide and protector of important relations four strong fishing-gut sutures are inserted by a curved hernia needle about half an inch apart, from within outwards through Gimbernat's ligament and the external oblique, the ends being retained outside the aponeurosis. The free ends are threaded in rotation on a hernia needle with an opposite curve and are carried from within outwards well into and through the substance of the conjoined tendon, these ends being similarly retained outside the sheath of the tendon. A straight aneurysm needle is next made to enter the suture hole in the tendon, passed across, and made to emerge through the corresponding suture hole in the external oblique. The end of this portion of suture is attached and drawn across and out through the aperture of entry of the needle; thus, the two ends emerge from the same hole in the sheath of the tendon and form a circular submuscular suture. When the four are thus applied—and this does not take a quarter of the time to insert that it does to describe—the assistant draws the cord downwards and the sutures are tied with sufficient force to draw the tendon backwards in front of the vas to Gimbernat's ligament, care being taken in the adjustment of the lower sutures not unduly to compress the vessels of the cord. The ends of the stitches are then snipped off, when the knots retreat into the substance of the conjoined tendon and are sealed over by a catgut suture through each aperture. The operation, which occupies usually from 10 to 15 minutes, is concluded by uniting the skin wound with a continuous blanket suture.

It may be germane to the subject of this paper to mention the treatment of adhesions in hernial sacs. In recent hernias adhesions may be brushed off with a piece of sponge or gauze or coaxed away with the pulp of the finger; in old cases it is quite another matter, for generally one finds the omentum so incorporated in the sac wall that a portion of the former must be excised and in performing this little operation it is most desirable to avoid the practice of surgeons who insert interrupted ligatures with sharp instruments, leaving a clear space between each; it is needless to state that this kind of procedure necessitates a fumbling procedure of ligaturing in the mass when the unoccluded vessels begin to spirt. Instead the omentum should be held up and kept well spread out by an assistant while the surgeon introduces a medium silk interlocking ligature, care being taken not to puncture a vessel with the point of the blunt introducer. The loss of one patient from post-operative omental bleeding is my reason for inviting serious attention to the matter.

---

[1] THE LANCET, August 26th, 1899, p. 554.

In conclusion, the advantages which I claim for my hernial operation are that the two most suitable structures for effective barrier formation in the inguinal region are utilised without any anatomical sacrilege and without the formation of potential spaces which so often prove a bugbear to aseptic surgery.

Buenos Ayres.

A CASE OF APPENDICITIS WITH GENERAL PERITONITIS;

RECOVERY AFTER REMOVAL OF APPENDIX, FOLLOWED BY SECONDARY INCISION INTO THE CÆCUM FOR EXTREME PARALYTIC DISTENSION.

By FRANK COLE MADDEN, M.B., B.S. Melb., F.R.C.S. Eng.,

PROFESSOR OF SURGERY, EGYPTIAN GOVERNMENT MEDICAL SCHOOL SENIOR SURGEON, KASR-EL-AINI HOSPITAL, CAIRO.

The following case presents many interesting features and illustrates the grave complications that may result from appendicitis and the possibilities of recovery.

A man, aged 35 years, an American travelling in Egypt, was suddenly seized with pain in the abdomen and rapidly developed all the classical symptoms of appendicitis. I first saw him in consultation with Dr. F. M. Sandwith at the request of Dr. May, with whom he was travelling, on Feb. 19th, at 9 A.M. He was then in great pain and had a general distension of the abdomen, but no definite tumour could be made out. We at once decided upon operation. This was performed in a nursing home a few hours later, within 36 hours of the onset of symptoms. Although it was a first attack, on opening the abdomen by a curved incision in the usual situation thin lymphy pus at once escaped as soon as the peritoneal cavity was reached. There were considerable distension of the whole of the intestines and intense general peritonitis. The appendix was found very deeply placed in a pouch to the outer side and behind the cæcum and was with difficulty removed. There were patches of almost gangrenous inflammation on the cæcum and the adjacent coils of small intestine. The appendix itself was soft and gangrenous and contained two large concretions, just above the lower of which was a ragged perforation. There had been no attempt to shut off the appendix area from the general peritoneal cavity either by lymph or by adhesion of coils of intestine. The appendix was ligatured close down to the cæcum and removed, but all attempts to cover the stump with peritoneum were unsuccessful as the sutures cut through the soft inflamed tissues at once. Pus welled up everywhere between the coils but tended to collect towards the pelvis and in the pouch which contained the appendix. The peritoneal cavity was not washed out but the pelvis and the pouches round the cæcum were gently swabbed out with sterilised gauze and a gauze drain, running down to the stump of the appendix, was brought out through the middle of the wound in the abdomen, which was sutured in layers.

The day after operation there was a great improvement in all the symptoms. The pulse was good (82) and the temperature was 98·8° F. (103° before operation), but there were still a good deal of abdominal distension and rather troublesome hiccough. After an enema of soap-and-water and turpentine much flatus and some fæces were passed with considerable relief. One fluid ounce of peptonised milk was given every hour by the mouth, the quantity being gradually increased as there was no vomiting. One-fiftieth of a grain of strychnine was given hypodermically every four hours, the evening dose combined with one-quarter of a grain of morphia.

The wound was dressed after 48 hours and the drain renewed, though there was very little discharge. Small doses of calomel (one-tenth of a grain) were administered on the following day every half hour for three doses and then hourly until the bowels were moved. The patient's condition remained fairly satisfactory for six hours after the operation, but then the scene changed; the whole peritonitic blaze seemed to light up again and with it the distension rapidly increased to an alarming extent. Distended transverse colon could be made out nearly to the nipple line on both sides and there was considerable respiratory difficulty and cardiac distress. The temperature was 104° F., the pulse was 140 and markedly peritonitic, and the general condition became very grave. Vomiting also set in accompanied by hiccough and the vomited matters became rapidly fæcal. Large quantities of dark-brown fluid were pumped up which on standing precipitated a thick brown deposit of fæces and emitted a most offensive fæcal odour; in fact, the vomit consisted of pure fæces. During the night the distension appeared to become even greater than before in spite of turpentine enemata, strychnine injections, fomentations, turpentine stupes, &c., and the fæcal vomiting was practically continuous. The patient really appeared to be dying, but at 5 A.M. on the following morning, Feb. 20th, in response to Dr. May's earnest appeal "to try to do something," I removed the middle sutures of the abdominal wound and made an incision into the cæcum, which presented in the depths and which I had no hesitation in opening *in situ*, as I felt certain that all the parts in the neighbourhood must have become adherent all round and so have shut off the area of operation from the general peritoneal cavity. A large quantity of fæcal matter and brownish discharge and flatus came away at once from the incision and continued to do so for several minutes. The material obtained from the cæcum and the stomach was identical in character. The tube of an irrigator was then passed into the rectum and the whole of the large intestine was thoroughly irrigated with boric lotion, which all came away by the wound in the cæcum. To prevent any possible risk of leakage of fæcal matter into the peritoneal cavity four anchoring sutures were inserted to keep the cæcum in close contact with the abdominal wall. At the same time the patient was made to swallow two large draughts (one pint) of warm water, which were soon returned but fulfilled their purpose of washing out the stomach very thoroughly, and from that time the fæcal vomiting completely ceased. From the moment of the cæcotomy the patient's condition improved, his temperature gradually returned to normal, and all the grave symptoms subsided. The wound was left widely open and packed with gauze to induce it to heal by granulation from the bottom, while the fæcal fistula discharged freely in the centre. Apart from some irritative cough and occasional rather obstinate hiccough the further progress of the case was uneventful, and gradually more and more of the fæces were passed by rectum. On March 11th the skin and subcutaneous tissues around the whole area of operation were infiltrated with Schleich's fluid and several deep silkworm-gut sutures were inserted to approximate the granulating surfaces of the sides of the wound, leaving a small opening in the centre at the site of the fistula. The wound gradually filled up with granulations and later an attempt was made to destroy the redundant everted mucous membrane by frequent applications of silver nitrate. Finally, the projecting ring of membrane having been thus destroyed two rows of mattress sutures of fine silk were inserted across the fistula and completely closed the opening. This little operation was not, however, a complete success, as the middle sutures cut through and the fistula was re-established to some extent but was of much smaller calibre. A further attempt of the same kind also failed and the patient left for Europe in very good general condition but with a rapidly closing cæcal fistula. The bulk of the fæces passed by rectum, the discharge from the cæcum being soft and semi-fluid and only profuse to any extent at night.

The case is of interest for several reasons, but mainly from a practical point of view, because of the patient's recovery from an apparently hopeless condition. There is also the history of a first attack of appendicitis going on within 36 hours to a general peritonitis, which teaches the lesson of the dangers of delay in operation on these fulminating cases, and who is to say what course any attack of appendicitis will take? Further, the great improvement following the original operation, in spite of the fact that the peritoneal cavity was not washed out and was only partially drained, shows in this instance, at any rate, that the confidence we have in the power of the peritoneum to take care of itself is not misplaced, even though the membrane be already in a condition of intense inflammation.

I have often thought whether, if I had done an enterotomy at the first operation and perhaps injected sulphate of magnesia into the bowel as well, the further progress of the case might not have been quite satisfactory, although I did not think at that time that the distension was sufficiently marked to justify such a procedure. It seemed that a fresh wave of peritonitis occurred after seven days and this, rather than any intestinal condition, probably determined the excessive distension, for the bowels were acting fairly well at the time of the onset of the alarming symptoms. The intestinal obstruction was due entirely to the paralytic distension for which any operation other than the cæcotomy would have been impossible owing to the patient's exceedingly grave condition. The opening of the cæcum was done entirely without anæsthetics of any kind and it is rather an interesting fact that the patient has not the slightest recollection of what was happening during the few days when his life was trembling in the balance. He does not even remember being sick, which was a mercy, as the fæcal vomiting was anything but pleasant. All the ordinary methods for combating distension having failed and realising that an enterotomy was the only possible treatment but that it was quite impossible to attempt an abdominal section owing to the patient's condition, it occurred to me that the cæcum *must* be safe, for it must certainly be adherent at one point in the depths of the wound after the drainage and the matting together of the parts around it which must have occurred as the peritonitis subsided. Lockwood[1] writes: "I have seen my colleagues Harrison Cripps and Bruce Clarke in desperate cases of flatulent distension successfully establish a temporary opening in the cæcum or ileum. Hitherto, I have not been obliged to resort to this expedient after appendectomy." It must, however, be of comparative rarity that the recrudescence of general peritonitis a few days after an operation of this nature gives rise to such a treatable condition as paralytic distension, unless it leads to the formation of a localised abscess; for, unfortunately, cases that flatter the surgeon so much by their great improvements for a few days so often end fatally most insidiously, allowing him only the opportunity of making a diagnosis but without offering him justification for further operative treatment of any kind.

My best thanks are due to Dr. Sandwith for his valuable help in the after-treatment of the case, to Dr. May who was untiring in his devotion to his friend and irrepressible in his efforts to stimulate me to fresh endeavours, and to Dr. Beebe, in whose capable hands our patient eventually left Cairo. Finally, to Dr. Keen of Philadelphia, who happened to be passing through Cairo shortly after both operations, we are all indebted for his powerful moral support and for his kindly encouragement and advice.

Cairo, Egypt.

Complaints against a Public Vaccinator.—At the meeting of the Chipping Sodbury Board of Guardians held on May 21st a letter was read from the Local Government Board stating that their vaccination inspector had reported that one of the public vaccinators of the Chipping Sodbury Board of Guardians had not performed any vaccinations during the quarter ending March 31st, 1900, nor during the quarter ending March 31st, 1901, and that he did not comply with the directions of paragraph 6 of the third schedule of the Vaccination Order of 1898 as to the aseptic precautions to be taken in vaccination. The guardians eventually decided to forward the letter to the public vaccinator.

National Sanatorium for Consumption, Bournemouth (Open-air Treatment).—The annual general meeting of governors of the National Sanatorium for Consumption, Bournemouth, was held on May 8th, at the Westminster Palace Hotel, Mr. Arthur F. Jeffreys, M.P., being in the chair. The annual report of the committee, with the statement of accounts for the year 1901, was placed before the governors, showing a deficiency of £431 instead of a balance in hand, as in the three preceding years. This was attributed mainly to a falling-off in donations and to special expenses connected with efficiently carrying on the open-air treatment of patients now sucessfully adopted for some years past. Measures were considered for meeting the deficiency and for obtaining increased funds for carrying out the proposed extension of the building at a cost of about £1200 and it was resolved that a further appeal for donations and subscriptions should be made to the public.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A CASE OF PERFORATED GALL-BLADDER SIMULATING PERFORATED GASTRIC ULCER.

(Under the care of Mr. G. P. Newbolt.)

Perforation of the gall-bladder is generally the result of ulceration due to the presence of one or more gall-stones, but Dr. Norman Moore has described a case[1] in which there was very extensive ulceration of the mucous membrane of the gall-bladder without the presence of any concretion. In the following case perforation occurred without any previous symptoms pointing to the existence of biliary calculus. This also happened in a case recorded by the late Dr. W. M. Ord.[2]

On March 15th, 1902, Mr. Newbolt saw a married woman, aged 48 years, in consultation with her medical attendant. She was very ill and was evidently suffering from some grave abdominal lesion. She had suffered for some years from attacks of dyspepsia but had never had hæmatemesis or jaundice. There was nothing pointing to any affection of the gall-bladder. For about a week before Mr. Newbolt saw her she had been suffering from an attack of dyspepsia and for two nights had not slept on account of the pain in the abdomen which she referred to the umbilicus. During this time she had only taken a little liquid food. At 10 A.M. on March 15th she was seized with agonising pain at the umbilicus which caused her to double up and to collapse. On examination three hours later her pulse was 110, feeble, and easily compressible; her abdomen was not distended but was hard like a board and tender all over, and her temperature was 102° F. The liver dulness was present and her bowels had acted two nights previously. She was an unhealthy and delicate-looking woman. Having come to the conclusion from the acute pain and sudden collapse, together with the history of dyspepsia, that a gastric ulcer had perforated Mr. Newbolt advised the performance of an exploratory laparotomy, and as it was impossible to do this in her home she was removed in an ambulance to the Royal Southern Hospital.

The abdomen was opened in the middle line above the umbilicus and at once yellow, turbid, serous fluid was seen amongst the coils of small intestine. The abdominal muscles were very rigid though the patient was deeply under chloroform and some difficulty was experienced in getting the stomach into the wound. A thorough examination of this organ back and front revealed no perforation and so it was distended with a pint of water passed by means of an œsophageal tube. The fluid, however, did not escape and it was evident that the stomach was not at fault. The incision was therefore enlarged down below the umbilicus, and on introducing the hand into the right flank a large gall-stone was felt in the cystic duct, as well as a very much distended gall-bladder covered in by the liver which was enlarged and to the under surface of which the gall-bladder was adherent. There was a minute hole in the gall-bladder from which thin, puriform fluid was escaping. A transverse incision was next made into the right loin; the gall-bladder was exposed and opened freely and six large stones were removed, one being impacted in the cystic duct. It was necessary to cut away the sloughing part of the gall-bladder which was behind and to the inner side of the fundus; the edges were then inverted and sewn over, completely closing the cavity. Having thoroughly cleansed the abdominal cavity a gauze pack was left in leading down to the gall-bladder and the right flank was drained by placing a tube

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

National Association for the Prevention of Consumption and Other Forms of Tuberculosis, Dublin Branch.

A MEETING of the executive committee of the Dublin branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis was held on March 25th to consider an important proposition brought before it by Sir Christopher Nixon, President of the Royal College of Physicians of Ireland, with regard to the establishment of a sanatorium for the treatment of consumption among the poor of Dublin and its suburbs. Sir Christopher Nixon mentioned that the sisters of mercy had recently acquired the house and demesne of Beaumont, embracing some 110 acres, for the purpose of providing a convalescent home for the patients of the Mater Misericordiæ Hospital. It occurred to him to suggest that advantage might be taken of the site to establish a sanatorium for the reception and treatment of cases of consumption among the destitute poor who could not be treated with hope of beneficial results in a general hospital. He explained that the sisters of mercy were ready to offer their services in taking charge of the institution and nursing the patients on the following conditions: (1) that the sanatorium should be built and fully furnished, and (2) that the expenses should be defrayed for the maintenance of the patients and the proper working of the institution. Sir Christopher Nixon also laid before the committee a letter from Dr. Walsh, the Roman Catholic Archbishop of Dublin, in which he (Dr. Walsh) stated that he approved of the project and would do anything he could in aid of it. The following motions relative to the project were passed unanimously :—

Resolved—That the Council of the Dublin Branch of the National Association for the Prevention of Tuberculosis have heard with deep interest and sympathy of the probability of the establishment of a sanatorium in the vicinity of Dublin in which the destitute poor of the city and suburbs afflicted with pulmonary consumption may be satisfactorily treated in the early and remediable states of that complaint.

Resolved—That the council are of opinion that the advantages likely to accrue to the public health from the establishment of the proposed sanatorium are of a twofold kind: first, far-reaching benefit to the patients themselves; secondly, a widespread influence for good from an educational standpoint, patients and their families being taught how to prevent the spread of the infection of tuberculosis.

The Royal Victoria Hospital, Belfast.

At the annual meeting of the friends of this institution, which was held in Belfast on March 18th, it was reported that 2080 patients had been treated in the hospital during the year and 354 in the convalescent home, 29 in the consumptive department, and 137 in the children's hospital, making a total of 2600 cases; in addition to which 25,463 patients had been treated in the out-patient department. The receipts from all sources were £12,487 9*s.* 5*d.* and the expenses were £11,589 5*s.* 2*d.* The necessary expenditure exceeds the legitimate income by £2051 15*s.* 9*d.* The new hospital will be ready early next year and the better and greater accommodation it will afford must necessarily involve a much larger expenditure: therefore it is necessary to make timely preparation for this additional outlay. A cordial vote of thanks was given to the medical and surgical staff for their services during the year.

Small-pox in Belfast.

So far only one case of small-pox—introduced from Glasgow—has occurred in Belfast. At the meeting of the Belfast Guardians on March 18th a resolution was passed requesting the Local Government Board to make arrangements by which persons suffering from any infectious disease shall not be removed from the gaol, where there is sufficient hospital accommodation provided, as there is grave danger incurred in the transit of these cases through the centre of a crowded city. The guardians say that the police authorities have no right to rid themselves of responsibility by driving a small-pox patient from the gaol to the workhouse through a crowded city.

Ulster Medical Society.

An adjourned meeting of this society was held in the Pathological Laboratory of Queen's College, Belfast, on March 20th, Professor W. Whitla, the president, being in the chair. Dr. J. McLiesh read a paper on the Blood in a Case of Skin Disease; Dr. R. Allen read a paper on Granular Leucocytes in Tumours, illustrated by microscopic sections; Dr. H. L. McKisack and Lieutenant D. McCay, I.M.S., read Notes of Pyelitis in Young Children; Mr. R. J. Johnstone showed the organs from a case of Molluscum Fibrosum with Fibrous Tumours in the Stomach and a specimen of a rare form of Enlargement of the Prostate; Dr. Eleanor R. Sproull gave a demonstration of the Structural Changes in the Liver and Kidneys in a case of Acute Yellow Atrophy of the Liver; and Professor J. Lorrain Smith demonstrated the Deposition of Iron in the Liver in a Case of Pernicious Anæmia.

The Royal Commission on Irish University Education.

The commission is to begin its sittings in Belfast, in the Library of Queen's College, on April 2nd. The members are to be entertained to dinner by the Professors of Queen's College and the President has issued invitations for an "afternoon" to meet the Royal Commissioners. It is understood that several very important witnesses will be examined and that the case of the Northern College will be fully presented.

April 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Method of Producing Analgesia of a Tooth for Extraction.

M. Regnier and M. Didsbury recently communicated to the Academy of Medicine a new method of analgesia in dentistry which does away with the use of cocaine, of carbolic acid, or of any of the well-known anæsthetics which are all more or less toxic, and in the use of which the patient runs a risk of poisoning quite out of proportion to the insignificant operation of an extraction. The method is to use an electrical current of high frequency which produces absolute insensibility of the tooth. The current is applied to the tooth by means of a gutta-percha cap lined with gold leaf, and in this way the field of application of the current is limited to the tooth which it is desired to extract. Perfect analgesia is obtained in a few minutes and the tooth can be removed without the patient feeling anything. The application of the current is easy and harmless and the method would seem capable of application to other operations of minor surgery.

A Federation of French Anti-Tubercle Societies.

On March 16th there was held in the hall of the Society of Civil Engineers, the President of the Republic being present, a formal inauguration of the federation of all French societies for the prevention of tuberculosis. These societies, which previously have wasted their strength by acting separately, will now be increased in power by being united. Representatives from 76 societies and 37 cities were present. The President of the new federation is Professor Brouardel and the objects of the federation are to favour the spread of knowledge about tuberculosis and the various methods for its prevention and to unite for the purposes of effective action all societies and persons who have studied the subject from its different aspects. The example of England, where the mortality from tuberculosis has declined by 45 per cent. in 40 years, and of Germany, where it has declined by 12 per cent. in 10 years, should give great encouragement to the struggle in a country like France, blessed in the possession of a beautiful climate, to enjoy which the sick of all nations come in the hope of cure. The central bureau of the federation will serve as a link between the different sanatoriums and as a guide to patients. One case of tuberculosis, for instance, will require treatment in the isolation ward of a hospital; another will do better at a seaside sanatorium and another at a high altitude; another will be so far convalescent that he will be sent to an agricultural colony. The Bureau will in addition organise a system of relief for patients and for this purpose friendly societies will be asked to contribute as well as ordinary charitable persons. The railway companies, so many of whose employés are affected with tuberculosis, will be asked to subsidise local sanatoriums in the respective districts served by them and the military charities will also be asked to help so that soldiers who are on their books may be sent to a sanatorium instead of being allowed to spread infection broadcast by remaining at large.

Professional Secrecy and Hospital Practice.

The Consultative Committee of the Assistance Publique has just formulated an answer to a problem laid before it by Dr. Bonnaire, the obstetric physician to the Lariboisière Hospital. In pursuance of this decision a circular has been sent out to all the hospitals pointing out that professional below the kidney. The patient stood the operation well and promised *at first to make a good recovery; she sank, however,* five days after the operation, apparently from exhaustion. There were troublesome vomiting and slight distension unrelieved by salines or enemata. As far as the wound went all was satisfactory and there was no extravasation. The *gall-bladder was shut off from the general peritoneal* cavity and there were no signs of general peritonitis.

Remarks by Mr. NEWBOLT.—In those cases in which a stone ulcerates through the gall-bladder mischief is usually avoided by the adhesions which glue the affected organ to neighbouring parts, either the viscera or the abdominal wall. There are several cases on record by different observers in which acute peritonitis has been set up by a perforation of the gall-bladder the contents of which have escaped into the abdominal cavity, and there are one or two instances also which have been successfully operated upon. In the case related above it was impossible to make a diagnosis from perforated gastric ulcer and for this reason, though the result was fatal, I think that it is desirable to publish it. A close interrogation of the patient never elicited any history of gall-stones and she had always referred her pain to the region of the stomach. She had never been jaundiced at any time and was most definite on this point.

ROYAL NAVAL HOSPITAL, PLYMOUTH.

A CASE OF MULTIPLE ABSCESSES IN THE LIVER SECONDARY TO PERFORATING ULCER OF THE STOMACH.

(Under the care of Staff-Surgeon EDWARD R. D. FASKEN, R.N.)

MULTIPLE abscess *of the liver is* a very rare complication of gastric ulcer, whether perforated or unperforated, and very few cases have been put on record. C. Murchison has published an instance of this condition [1] but in that case general pyæmia also occurred. In the following case no signs or symptoms pointed to the existence of gastric ulcer. This latency occurs in no small proportion of cases. Savariaud [2] estimated the latent cases to form 20 per cent. of all cases of gastric ulcer.

On Feb. 22nd, 1902, an able seaman was admitted into the Royal Naval Hospital, Plymouth, under the care of Staff-Surgeon Fasken, complaining that he had suffered from abdominal pain on or off for about two years, situated chiefly in the right iliac fossa near the umbilicus. The bowels were *acting irregularly. There was no history of vomiting.* The temperature was 102° F. The hepatic dulness in the right mammary line measured five inches vertically. There was considerable jaundice. The pulse was 76. The abdomen was somewhat distended and palpation caused a good deal of pain, especially over the cæcum. The tongue was thickly coated. Fomentations and a glycerine enema were prescribed with bismuth and the patient was placed on a milk diet. On the evening of March 1st he had a rigor and complained of severe pain over the hepatic area. The temperature was 102·2°. On the 3rd he had more rigors and complained of a tender spot over the liver in the region of the gall-bladder. Paroxysmal rigors came on at irregular intervals and were followed by profuse perspiration with great prostration. The tongue became dry and brown and tenderness over the liver area was greatly increased. On the 22nd he vomited a quantity of greenish bilious fluid during the night. Two exploratory punctures were made into the liver below the costal margin but only a few drops of blood were extracted. On the 24th two more exploratory punctures were made behind in the eighth intercostal space, but again with a negative result. A few days later ascites and œdema of the lower extremities appeared, also a distinct pleuritic rub was heard on the right side. The hepatic dulness in the right mammary line was now six and a half inches but the enlargement was uniform and free from nodulation. On April 10th he was much weaker and greatly emaciated. The skin and conjunctivæ were markedly jaundiced. There was great tenderness on pressure below the lower margin of the right ribs, with incessant severe pain across the upper part of the abdomen and between the shoulders, which had to be relieved by injections of morphia. The area *of splenic dulness was increased. The above* symptoms all became gradually more aggravated. He still had irregular paroxysms of rigors, followed by fever and sweating. He gradually sank and died on the 15th.

Necropsy.—At the post-mortem examination there was found near the œsophageal end of the stomach on its anterior surface a circular ulcer of the size of half a crown with its edges slightly elevated and undermined. From the base of *this ulcer a small* fistulous channel passed into an abscess of the size of a hen's egg in the right lobe of the liver close to the gall-bladder. The liver was enlarged generally, weighing 96 ounces; both lobes were thickly studded with abscesses varying from the size of a pea to that of a walnut and containing *thick yellow pus; the abscess cavity in connexion with* the stomach was, however, filled with food material. The intervening hepatic tissue was very hyperæmic. There was evidence of considerable surrounding peritoneal inflammation; the stomach, transverse colon, duodenum, pancreas, and liver (the under surface) were all firmly matted together, the great omentum being adherent to the upper surface of the left lobe of the liver. The spleen was large, dark, and firm. The pancreas was hard and lumpy and was firmly adherent to the left kidney and spleen. The abdomen contained a quart of yellowish serous fluid. The right pleural cavity contained fluid and was encroached upon by the enlarged liver, the right lung being pushed up and collapsed and adherent at the base. The other organs were healthy.

Remarks by Staff-Surgeon FASKEN.—This case is of interest, as although the symptoms pointed to the probability of a pyæmic abscess in the liver, inasmuch as the patient had never been abroad, nothing in the history of the case led one to suspect ulceration of the stomach. There had never been any hæmatemesis or even definite history of vomiting, the only symptom complained of being general abdominal pain.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Etiology of Leprosy as observed in the Soudan and in South Africa.

A MEETING of this society was held on May 27th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. T. J. TONKIN made a communication on Some General and Etiological Details concerning Leprosy in the Soudan. Mr. Tonkin began his paper by defining briefly the particular leper area referred to—namely, the Soudan—and by giving a short sketch illustrative of the extent to which the disease prevailed there. Enormous quantities of the disease were to be found in the Soudan and northern Nigeria—an area of 500,000 square miles. *He then passed on to describe* what he believed to be the ordinary course of contagion in the Soudan. He had satisfied himself that it was a process of mediate contagion in which clothes played the chief part of vehicles. The customs of the Soudanese lent themselves to this. In the Soudan clothes were almost never washed. The native cloth was woven in narrow strips which were subsequently sewn together to make a piece. Cloth made in this way did not stand much washing. Rich men bought their clothes new and when they became soiled sold or gave them away. Through the working of this custom any one robe might have during its existence an almost unlimited number of owners, any of whom might have suffered, among other communicable diseases, from leprosy. Natives did not mind buying and wearing robes that had been worn by mutilated lepers. They might even see them *stiff with leprous* exudations without thinking it necessary to have them washed. Such robes as these they would wear all day and roll about at night with nothing between the prominences of their bodies and the hard matted surfaces which served them as beds but these leprous garments. Mr. Tonkin applied these facts to the explanation of the mode of dissemination of the disease by pointing out that it was exactly upon those prominences that (in the Soudan at least) the first sign of the disease most usually appeared. In attempting to account for the predisposition to leprosy Mr. Tonkin laid down what he referred to as the anitrogenous theory. In every *leper field in the world if the average diet* of the affected classes were tabulated it would in each case probably present the same specific defect. That defect was the lack of a sufficient quantity of nitrogenous elements. To the effect of this dietetic imperfection he traced the liability to the disease. This factor of diet could not be regarded as the only one, but he considered it as the essential one. Turning to the question of heredity, out of 220 of Mr. Tonkin's cases in only 18 could an hereditary predisposing tendency be traced, and he did not regard hereditary predisposition as a necessary, or even an important, causal factor in the disease.

---

[1] THE LANCET, Feb. 29th, 1868, p. 278.

[2] Robson and Moynihan: Diseases of the Stomach, p. 104.

Mr. JONATHAN HUTCHINSON made a communication on Leprosy in Cape Colony and Natal. The paper was based upon the experiences gained during a tour in Cape Colony and Natal during the months of December, 1901, and January, February, and March, 1902. The tour was undertaken in order to examine as to the prevalence and distribution of leprosy in South Africa and more especially as to its connexion or otherwise with the Cape fish-curing trade. Among other conclusions arrived at by Mr. Hutchinson as the result of his investigations were the following:—1. That leprosy was almost, if not absolutely, unknown in South Africa before the Dutch occupation of the Cape; and that before the record of the first cases the Dutch had brought over Malays from Java to establish a fish factory at Cape Town. 2. That salt fish with rice was the staple food of the Dutch farmers and their Hottentot slaves at the time that leprosy was first observed, in 1756; and that since the first cases were observed the disease had gradually spread around Cape Town, in the first instance, and ultimately over almost the whole of what was now British territory, including the Free State and the Transvaal. 3. That the disease had prevailed very slightly in towns such as occurred in highly infectious maladies, but it had affected chiefly agricultural labourers; and that the disease, although very widely spread, was unequally distributed—dotted about amongst the agricultural and mining populations throughout Cape Colony who used very largely as food badly cured salt fish. 4. That in the Kaffir kraals of Natal there was good reason to believe that the disease was communicated from person to person and especially to young children, it being suggested that the mode of communication was by eating food direct from a leper's hand contaminated by secretions containing the living bacillus. This it was proposed to call "commensal communication." It seemed probable that in Cape Colony *de novo* production—i.e., without hereditary transmission or direct infection—by the use of salt fish had been the common cause of the disease, whilst in Natal commensal communication had been more frequent. The two hypotheses of fish-production and commensal communication taken together satisfactorily explained several difficulties which had hitherto been felt in reference to leprosy, such, for instance, as the non-occurrence of spread in well-civilised communities and its irregularity and uncertainty even amongst the most careless; the frequency with which young children suffered; the universally observed but varying disproportion of the sexes; and the scattered distribution of the disease without, as in the case of South Africa, any foci of great prevalence. Turning to the question of heredity, the facts which had come to his notice did not support the idea that this played any important part in the production of the disease. The chief object of the present paper, however, was to maintain two principal propositions. The first was that leprosy was undoubtedly communicable from person to person but that the mode of its communication was peculiar and did not come under the head of contagion properly so called. The second was that, although personal communication could not, of course, explain the *origin* of any disease, the facts as regards the origin and distribution of leprosy in South Africa strongly favoured the belief that it could arise without direct personal contagion as a specialised form of disease, possibly tuberculosis, from the eating of imperfectly cured fish. The facts which convinced Mr. Hutchinson on the first point were the following. Near the village of Howick, in Natal, on the open veldt, he saw young lads unquestionably the subjects of leprosy who had never left their native kraals and concerning whom it was morally certain that they had never eaten salt fish. They were living in the same kraal with adults who were the subjects of leprosy and who had probably obtained it in Cape Colony. Subsequently in other parts of Natal he met with precisely similar facts. Now, leprosy was not endemic in Natal; it could not be suggested that there were any conditions as regards food or mode of life which could conduce to it. The kraals were widely separated from each other on the open hillside and their inhabitants had usually enjoyed good health. Leprosy was of recent introduction and was met with only very sparingly. In all instances in which young persons were its subjects there was the history of its introduction into the affected kraal by an adult who had previously sojourned in a fish-eating district. The inference seemed inevitable that the disease in these cases had been communicated from one person to another. Nowhere, however, had it spread to many. Its incidence appeared to have been most erratic. A few had been taken and a great many who had apparently been equally exposed had been spared. The facts which seemed to support the hypothesis that in all cases in which the disease spread from person to person the bacillus was received by the stomach were very strong. The first symptoms of leprosy were almost always those of a blood disease. There was never any primary sore or other indication of local infection. The earliest phenomena, whether affecting the skin or the nervous system, were, as a rule, bilateral and implied blood contamination. It was impossible to believe in communication by the breath, for attendants in leper-houses and others who might be in constant and close communication with lepers never took it. It was also for the same reason impossible to believe in contagion through the skin. It was very rare for both husband and wife to suffer; and many experiments in inoculation had been tried without result. A comparison between syphilis and leprosy was also against the idea of the inoculability of the latter. These facts had been felt to be so strong that prior to the discovery of the bacillus there was a very general disbelief in the contagiousness of leprosy; and this was the verdict given by the Royal College of Physicians of London after a detailed inquiry. They were now confronted with the proved existence of a parasite and with evidence beyond dispute that in some way the disease could be communicated. The suggestion that the bacillus was received into the stomach by the direct contamination of food by leprous discharges met the requisite conditions. Such contamination of food was not likely to occur excepting under conditions of extreme carelessness as to feeding, and it was only amongst those who fed very carelessly that proofs of the communication of leprosy were met with. Amongst the cleanly communities of Europe and America, although there were plenty of leper patients who might serve as sources of infection, no such communication appeared to occur.—The discussion on the etiology of leprosy as raised in these two communications was adjourned until the next meeting on June 10th.

CLINICAL SOCIETY OF LONDON.

Inheritance of Recurrent Attacks of Jaundice with Hepatosplenomegaly.—Subsequent History of Three Cases of Colitis in which Right Lumbar Colotomy had been Performed Several Years Previously.—Annual General Meeting.—Election of Officers and Council.

A MEETING of this society was held on May 23rd, Mr. HOWARD MARSH, the President, being in the chair.

Sir THOMAS BARLOW and Dr. H. BATTY SHAW communicated a paper entitled, "Inheritance of Recurrent Attacks of Jaundice and of Abdominal Crisis with Hepatosplenomegaly." The observations giving rise to this paper were made upon two patients—a lad, aged 19 years, and his mother, aged 47 years. The youth when born was noticed to be a very delicate child and was pale and waxy-looking. At five years of age he was noticed to be jaundiced for the first time and since then there had been attacks of semi-jaundice lasting three or four days accompanied by pain in the upper part of the abdomen. For the last six years he had been troubled with indolent ulcers about the ankles. None of the patient's brothers or sisters suffered from attacks like these, though a brother had jaundice once in childhood. On admission into University College Hospital in 1899 the patient was found to be undersized for his age and looked anæmic and yellow. The liver was only moderately enlarged; the spleen was very enlarged, reaching two inches below the level of the umbilicus; there were signs of cardiac dilatation, more particularly of the left ventricle. The stools were repeatedly examined and were always found to be brown in colour. The urine very often was highly coloured; no bile could be demonstrated, but urobilin was detected spectroscopically. Examination of the blood showed signs of secondary anæmia. The temperature rose a little but was never more than 99·6° F. The boy was again admitted in May, 1901. There was practically no change in the size of the spleen but a slight reduction of the liver dulness below the right costal margin. A few glands were noticed in the neck. Besides a reduction in the number of red corpuscles of the blood and of the hæmoglobin, poikilocytosis, nucleated red corpuscles, and basophile cells were met with, and during the earlier part of his stay in the hospital the leucocytes numbered 14,000 per cubic millimetre. The woman had her first attack of jaundice when about five years old and had had repeated attacks since. With the jaundice there were pains in the upper abdomen and vomiting. She had one attack whilst pregnant with the child whose condition had been described. In an attack observed in September of last year the liver and spleen were found to be considerably enlarged. Urobilin and bile were absent from the urine. The examination of the blood showed the same characters as that of the son except that there were no nucleated red corpuscles. She had an indolent ulcer on the right leg, its onset dating before marriage. Both patients had always resided in England. There was no evidence in either case of septic infection; both mother and son were very temperate; during infancy a little brandy was given to the son daily for about a year. Very similar attacks occurring in three generations had been described by Dr. Claude Wilson and Dr. James Finlayson had called attention to the occurrence in several collateral members of a family. The special points to be noted in the above two cases were: (1) the chronicity of the affection, lasting in the son at least 14 years and being probably congenital and in the mother for a much longer period; (2) the occurrence of indolent ulcers in both cases; (3) the jaundice was always slightly present and underwent periodic intensification and was then associated with pain in the liver or spleen or in both; (4) the mother appeared to be a case of Hannot's cirrhosis of the liver, whilst her son could not but be considered as an earlier incomplete stage possibly of the same malady; and (5) finally, attention was called to the extremely guarded prognostic view to be held in such cases. The woman had grown to maturity and had had a family of several children and but for the disturbance caused by the periodic attacks of jaundice and abdominal pains was able to enjoy life. Sir Thomas Barlow added that the important point of these cases was the heredity of the disease. It was interesting to compare groups of inherited diseases; such, for instance, as Friedreich's disease which was an inherited form of locomotor ataxy. These inherited diseases differed from the corresponding acquired diseases. It would be premature to regard the cases which he and Dr. Shaw had recorded as biliary cirrhosis. He then discussed the relation of these cases to splenic anæmia. In the latter the liver was hypertrophied but there was no increase in the connective tissue.—Dr. H. D. ROLLESTON drew attention to an important observation of Boinet where in one family some members had well-marked hypertrophic biliary cirrhosis with chronic jaundice, while other members had no symptom of that disease but had an enlarged spleen and might be regarded as latent cases of that disease. The cases brought forward by Sir Thomas Barlow and Dr. Shaw appeared to lie between such cases and cases of splenic anæmia, especially as splenic anæmia might terminate in hepatic cirrhosis. There were two forms of splenic anæmia, one occurring in children related to intestinal toxæmia and the other occurring in adults not so related, and the latter terminated in "Batty's disease"—i.e., cirrhosis with recurrent attacks of jaundice. He inquired whether the jaundice referred to might be regarded as due to an exacerbation of toxic processes in the spleen, there being periodic intervals of immunity, or, on the other hand, was the jaundice thought to be mechanical?—Dr. HERBERT S. FRENCH insisted upon the fact that one of the chief features of splenic anæmia was the occurrence of hæmorrhages and this feature was wanting in the cases before the meeting. In reference to the count of leucocytes, which were said to have shown 10 per cent. of small leucocytes, he pointed out that the special characteristic of splenic anæmia was an increase to 30 or even of 40 per cent.—Dr. BATTY SHAW, replying, said that they had been unable to examine the serum of the patient's blood so that they could not say whether urobilin was present in the blood or whether it was true bile. In another case much urobilin was found in the urine, while in the blood only bile was found. He added that some of the counts had given a percentage of nearly 40 per cent.

Dr. W. HALE WHITE and Mr. C H. GOLDING-BIRD read a paper on the Subsequent History of Three Cases of Colitis in which Right Lumbar Colotomy was performed several years ago and in which the artificial anus was subsequently closed. Two of these (one membranous colitis and one chronic dysentery) were perfectly cured, remaining so after the artificial anus was closed In the third (one of membranous colitis) complete relief was given, the patient remaining well for 18 months after closure of the wound; she then relapsed and was not now materially benefited. The points to which the authors particularly directed attention were: first, that the operation was in some cases curative, acting by giving rest to the colon; secondly, that the artificial anus should be left open for a considerable time—in their cases one year, one and a half years, and two and a half years were the periods—and they were of opinion that in a severe case 10 years would not be too long; and lastly, reasons were given for always preferring a right lumbar colotomy to a cæcotomy. Irrigation was harmful rather than beneficial.—Dr PERCY KIDD asked whether irrigations were always found to be harmful in these cases, mentioning that in a recent case irrigations had seemed to do good for a time; injections of nitrate of silver had been tried but had to be abandoned. This patient appeared to be going on quite satisfactorily when hæmorrhage occurred with much pain and in the course of a few days she died quite unexpectedly. No post-mortem examination was allowed.—Mr. A. E BARKER mentioned the case of an elderly woman who was admitted to hospital with a huge abscess the result of appendicitis. This had been opened very widely by a colleague and she made a good recovery but with a large opening into the cæcum which gave rise to much trouble. He then cut down and anastomosed the lower part of the ileum to the colon. This was followed by great improvement but a very serious leakage persisted which prevented healing Finally, some months later, he again operated, cutting right through the colon, and she made a good recovery. That case had made him doubt whether the operation of uniting the ileum and the sigmoid flexure would be a success unless the latter were cut clean through.—Dr. SIDNEY COUPLAND asked whether right lumbar colotomy could be performed satisfactorily in the insane, adding that it would be a great boon seeing that colitis was very prevalent in large asylums, accounting for 10 per cent. of the total deaths.—Dr. NORMAN DALTON suggested that it might be well to open the lower part of the ileum rather than the colon in cases of colitis, and he related the case of a man who had had dysentery in South Africa and had undergone colotomy. Six months after the operation he was passing blood and mucus. On examining him they found a large hernia of the posterior wall of the bowel which effectually prevented anything from the ileum passing into the colon. The man was treated by irrigation and got well. Mr. F. F. Burghard then operated for the purpose of closing the wound and found that it was a piece of the ileum that was attached to the abdominal wall, and this enormously facilitated the closure of the bowel. In many of these cases the cæcum was much diseased and after colotomy the fæcal matter would get into the cæcum, whereas with an ileotomy it would not.—Mr MONIER-WILLIAMS related the case of a man who passed 20 hæmorrhagic stools every day with great emaciation in consequence The colon was opened on the right side and then he steadily improved The skin, however, became much excoriated by the liquid fæces and they had great difficulty in controlling the motions. He ultimately got quite well. With regard to irrigations he found that they improved matters greatly.—Mr. GOLDING-BIRD, in reply, admitted that in ulcerative colitis antiseptic irrigations were very useful and indeed indispensable. His remarks on this heading did not relate to membranous colitis He agreed that a better spur might be obtained from the ileum than from the colon.—Dr. HALE WHITE suggested that if anybody did make the anastomosis of the ileum into the sigmoid they would in many cases not get below the seat of the disease. After Mr Monier-Williams's experience one might well fight shy of opening the cæcum, the discharge from which was very acrid and irritating

The annual general meeting was then held The PRESIDENT referred to the loss which the *Clinical Society* had sustained in the death of Dr. W. M. Ord who was the type of a great physician, being an enthusiastic physiologist as well as a pathologist. The council's report showed the society to be in a flourishing condition and after the usual votes of thanks the following officers and council were elected for the session of 1902-3:—

President: Mr. F. Howard Marsh. Vice-Presidents: Dr. G. Vivian Poore, Dr. D. B. Lees, Dr. H. A. Lediard, Mr. A. E. Barker, Mr. R. Clement Lucas, and Mr. H. H. Clutton. Treasurer: Dr. Frederick Taylor. Council: Mr. J. Kingston Barton, Dr. J. Mitchell Bruce, Dr. C. W. Chapman, Dr. Lee Dickinson, Dr. S. H. Habershon, Dr. H. P. Hawkins, Dr. F. H. Hawkins, Dr. Percy Kidd, Dr. Hector Mackenzie, Dr. A. F. Voelcker, Mr. Gilbert Barling, Mr. Leonard A. Bidwell, Mr. Walter Edmunds, Mr. J. Hutchinson, jun., Mr. Raymond Johnson, Mr John D. Malcolm, Mr. H. Betham Robinson, Mr. Charters J. Symonds, Mr. C. S. Wallace, and Mr. F. C. Wallis. Honorary secretaries: Mr. Anthony A. Bowlby and Dr. William Pasteur.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases and Specimens.

A CLINICAL evening of this society was held on May 22nd, Mr. WATSON CHEYNE, the President, being in the chair.

The PRESIDENT showed a boy the subject of Congenital Syphilis who had suffered from Necrosis of his Nasal Bones and the bridge of whose nose Mr. Cheyne reproduced by the injection of paraffin having a melting point of 120° F. at the first injection and 104° for the second, after a week's interval, Mr. Cheyne having read of an injection by another surgeon with paraffin having a melting point of 104°. After the two injections the point of the nose, which had been held down during the operation, remained depressed and a presentable organ resulted. The operation was difficult on account of the rapid freezing of the paraffin immediately it touched the tissues. One objection to the parraffin at 104° was that it had a tendency to run into the space between the eyes, above the bridge of the nose. No inflammatory reaction had followed the injection. Greater improvement was possible but the skin was at present stretched to its limit.—Dr. LEONARD HILL thought cosmetic operations such as the present were justifiable, provided there was no risk of complications. He instanced several operations that had been done on the continent in which the paraffin had travelled into other parts subsequently. In one case shown before a meeting of the British Medical Association the results were splendid, but later some of the material escaped into the eyelids and 12 months after the operation the eyes were completely closed by the escaped wax.—The PRESIDENT, in reply, said that his injecting needle went practically down to the remains of the nasal bones. He used an ordinary serum syringe. The great point was to have the hot water quite close to the patient's face so that there was no time for the paraffin to cool. No pain was complained of during the injection.

Dr. A. MORISON showed a boy, aged 11 years, the subject of Early Mitral Constriction showing the triple rhythm. The boy had acute rheumatism two years ago and had had two attacks of chorea. He showed the usual phenomena of an ordinary mitral case. He did not think the triple rhythm could be regarded as diagnostic of the condition. The triple rub could be originated in pericarditic conditions, and under those circumstances the second sound might be spurious. Dr. Morison gave a review of the various theories held—namely by Sansom, Stacey Wilson, and others—and stated that in his view the triple rhythm was very much a matter of rate. If a patient with mitral disease and a triple rhythm was sat up in bed and the pulse-rate thereby quickened the triple character of the beat vanished. When the patient lay down and the pulse-rate slowed there was a quadruplication of sounds. He had verified that by sphygmographic tracings. In mitral cases one could sometimes, by the help of digitalis, produce quadruplication simply by slowing the heart.—Dr. SUTHERLAND thought Dr. Morison's theory plausible but it required carefully thinking out. He would have thought that the irregularity would have been more pronounced when the pulse-rate was increased than when it was slowed. He could only recall one case—that of a woman, aged 60 years, in which there was quadruplication of the heart sounds and in that case he thought the innervation of the heart was at fault. An important diagnostic point in his view was the duplication of the second sound. If Dr. Morison had a case of slightly accentuated first sound and definite reduplication of the second sound, would he be prepared to diagnose mitral stenosis fom those signs alone? His own view was that if those two signs were present the case was very likely one of mitral stenosis. In his experience, also, especially in children, the typical dilatation of the mitral orifice was more likely to be accompanied by irregularity of the heart's action than stenosis.—Dr. MORISON replied.

Mr. JAFFREY read notes of a case of Torsion of the Testicle and showed the specimen. The text-books mentioned that torsion of the testicle most frequently occurred in undescended testes but in the present case the testicle was completely descended. The patient, an errand boy, aged 15 years, came to the hospital with an ordinary hydrocele of the tunica vaginalis. The swelling was of the size of a hen's egg. When riding a bicycle he fell over the handle and struck his hydrocele which caused him much pain. A week later he again fell off his bicycle and struck the same part, causing him extreme pain, which brought him to the hospital. Hæmatocele was diagnosed. On operating Mr. Jaffrey found no hæmatocele, the swelling being more or less due to œdema of the scrotum. The testicle was enlarged, very hard, and black. On careful examination it was found that the testicle, instead of being attached to the posterior wall of the tunica vaginalis, had a mesentery of its own attached at the lower end of the epididymis. It was twisted three half-turns inwards. As it was a useless testicle he removed it.

Dr. E. CAUTLEY showed a specimen of Congenital Hypertrophic Stenosis of the Pylorus. He said that the disease was rare and was but seldom diagnosed during life. Dr. Cautley had seen two cases when he read his paper before the Royal Medical and Chirurgical Society three years ago and collected 18 others. Since then about 50 cases had been recorded. He believed the affection was commoner than was supposed because the present was the fifth which he had had under his own observation. The infant was two months old, the age at which such subjects usually died, and the stomach was decidedly large for that age. The pylorus, instead of being a thin ring, was three-quarters of an inch long and consisted of dense muscular tissue. Before it was laid open it formed a very definite tumour, in shape like the last joint of the little finger. From the stomach side it was funnel-shaped, the funnel being closed largely by a fold of mucous membrane. After death the constriction was so pronounced that only a fine probe could be passed and no fluid could be squeezed from the stomach through the orifice. The infant was apparently born healthy, at full term, and seemed normal. After a period varying from a few days to weeks the child started vomiting, but it was a regurgitant vomit; two or three meals would perhaps be kept down and then a very large quantity would be brought back. The appetite seemed unaffected. The tongue was clean and might remain so throughout the whole illness. The breath was not sour. Constipation was often, but not invariably, present and was often noticed at birth. Occasionally there was diarrhœa. No bile was found in the vomit. Towards the last such infants got very marasmic and died practically from starvation.—Dr. SUTHERLAND, Dr. MORISON, and the PRESIDENT discussed the specimen.—Dr. CAUTLEY replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Sleep in relation to Narcotics in the Treatment of Mental Diseases.—Surgical Treatment of Delusional Insanity.

AN ordinary general meeting of this society was held on May 21st, Dr. OSCAR T. WOODS being in the chair.

Dr. HENRY RAYNER read a paper entitled "Sleep in relation to Narcotics in the Treatment of Mental Diseases." He pointed out the importance of the subject at the present time, when so many narcotics were being introduced and supplied to the public with little check or control. He expressed the opinion that a considerable portion of the nervous and mental disorders of the well-to do classes was due to the abuse of those drugs. He alluded to the various theories of sleep and adduced arguments indicating the large share which the body took in the production of sleep. Contrasting sleep and narcotic stupor, he described the psychic state in the former as one of unconsciousness without loss of sensibility and the latter as unconsciousness with insensibility. Dr. Rayner said that the general physiological state in sleep was one of increased rather than decreased nutritional activity, while in narcotic conditions secretion, excretion, and general nutritional repair were greatly interfered with. The vaso-motor, respiratory, circulatory, and other centres were depressed. The reparative effects of sleep on the brain cells, as described by Hodge and others, was contrasted with the evidences of disordered nutrition found by Hamilton Wright, especially in the brain-cells of narcotised animals, corresponding to the psychic cells in man. The defects in insomnia, however caused, were summed up as consisting in defective nutrition of the *brain cells, variously associated with toxic conditions of the* blood, with anæmia and hyperæmia of the brain and irritation of it, either from the body or from the environment. The question was asked whether narcotics could be shown to be curative of these states of disorder, or whether benefit could be expected from their use, except in states of physical or mental pain from irremoveable conditions in the environment. Dr. Rayner arrived at the conclusion that in narcotic doses any good resulting from their use must be in spite of the disorder of nutrition to which they gave rise, and if given to produce sleep that object could be more satisfactorily attained by other remedial agencies, which helped at the same time to restore the associated vascular and nutritional conditions. He believed the occasions for the use of narcotics were very few, and stated that for many years he had rarely had occasion to use them. He hoped in a future paper to discuss the methods of treatment by which he had been able to obviate the use of narcotics.—Dr. G. F. BLANDFORD said it was evident that Dr. Rayner had a great prejudice against sedatives and narcotics of all kinds, but that was not his own view. He had been treating patients for 40 years, many of whom had come to him in a state threatening insanity, in which insomnia was a very marked feature, and he felt as certain as he could of anything that a great number of those patients had been materially benefited by the use of medicines given to induce sleep. Of course, such medicines could be abused and could be given until that state of insensibility had been produced to which Dr. Rayner referred. But doses could be given which would have a thoroughly therapeutic effect and produce a state which was indistinguishable from natural sleep. But it was necessary to select the drug suitable to the particular case. He was convinced that among the general body of the profession far too large doses of sedatives were given and that they were continued for too long a time. With so many drugs available chloral was now much less used than formerly. One of the best and safest was paraldehyde. At one time the only drug available for acute mania was morphia, which did not send the patient to sleep, and if it were pressed death resulted *from opium-poisoning, especially since the introduction of* hypodermic injection. There was the class of case where there was no danger of death from want of sleep and in which the giving of narcotics night after night prolonged the case. In such cases it was better to give no drug at all.—*Dr. G. H. SAVAGE said that the symptom* which more than any other he was consulted about was sleeplessness. Of course, if sleep could be obtained by natural means so much the better, but the cause of the sleeplessness must first of all be ascertained. One heard much about anæmia of the brain but in *many cases he was* certain that a nightcap of grog and a little food were more likely to produce sleep than sedatives of the opium type. He agreed that there were cases in which hydro-therapy was of the utmost use—namely, those already loaded with toxic agents, those who had taken *too much alcohol, or* who were gouty. *For* such patients a dose of calomel followed by saline waters and baths would be of great value in inducing sleep and curing the patient. It was a working axiom with him that in painful conditions opiates and narcotics assisted in procuring sleep, especially in *cases with mental pain.* Though opium generally upset the digestion the rest it procured was the means of the digestion being improved. He had seen extremely mischievous patients narcotised into dementia and on recovery from that get perfectly well. A morphinomaniac could be given an ounce of *bromide per day for several days* and be found to have recovered at the end of that time. One could say much the same of narcotics as of restraint. In years gone by his character was taken away because he declined to bow to the worship of non restraint. It had been *said of narcotics that they produced simply a form of laziness*—that the alienist thereby made a desert of the mind and called it peace. He agreed with Dr. Blandford that in many cases narcotics were of the greatest benefit in warding off threatened attacks of insanity.—Dr. FLETCHER BEACH said that his work lay *more in nervous diseases than in actual insanity.* In many cases of neurasthenia and brain fag, unless sleep could be procured very little could be done in the way of treatment. He practically always used sulphonal for the purpose and he had not been able to find any evidences of *emaciation or any kind of indigestion likely to lead to emaciation.* On the contrary, he believed it to be instrumental in keeping up the weight of the patient. He thought that it was wrong to give narcotics continually for weeks. He thought it important for all the bodily functions to be made active. In a case of *hysterical mania* he tried the effect of hyoscine injections, beginning with one-two-hundredth grain and working up to one-seventieth, and in three weeks the patient was cured.—Dr. T. B. HYSLOP said that it was important to know what normal sleep was, not from the physiological or pathological points of view, but from the clinical. He referred to the investigations of Russian and German authorities and the charts they had constructed, and spoke of the importance of distinguishing between restful sleep and that produced through the agency of narcotics. He had always been a little doubtful about the experiments of Hodge and the effects of fatigue upon the nerve cell of small animals. He thought that the effect of an electric current upon such a cell would be commensurate with the effect of lightning upon an ordinary person; and the amount of previous preparation of the cells was enough to make one sceptical about the results. He defended the practice of physical restraint. The great point, which he had verified by experiment, was that if one cut off the physical expression of emotions one also cut off the emotions themselves. The questions of food and the free action of the skin were important.—Dr. T. CLAYE SHAW thought the discussion had taken an experiential form, whereas he had hoped to have heard more scientific facts about sleep. Very little was known about either sleep or narcotics. Sleep was either a nervous or a vascular condition; and where insomnia was connected with the vascular state it was probably unwise to treat it by narcotics. He suggested that in many cases of insanity the highest functions were inactive, that those parts of the brain were really at rest. In such cases was it not wise to abstain from poisoning the cerebral cortex with narcotics?—Dr. R. PERCY SMITH referred to those violent cases which required to be dealt with at once in the patient's own home, of which he gave an instance. He thought Dr. Rayner would agree that in such a case a sedative was required. With regard to sulphonal, at Bethlem Hospital he had found it to give rise in some cases to indigestion and hæmatoporphyrinuria. Some patients could not sleep at nights and he thought that they *should be allowed to sleep* when they felt inclined. General practitioners as a body did not yet realise that other drugs would produce sleep without the very bad effects of morphia. It was undesirable to continue narcotics without giving the patient a chance to do without them.—Dr. ERNEST W. WHITE *spoke of the importance of a regular round of events* in asylum life as a factor in producing quiet nights. He believed that there were many forms of melancholia in which morphia was the sheet-anchor. In acute mania he had given up the exhibition of bromide and chloral *for many years, the cases were* taken for an hour or two's exercise and they gradually fell into line with the other patients and got to sleep without drugs.—Dr. J. S. BOLTON said that he had had considerable clinical and pathological experience of sulphonal. Pathologically for every case of *hæmatoporphyrinuria he had seen 10 of hæmatoporphyrinæmia.* The prolonged use of sulphonal was most pernicious from the point of view of auto-intoxication. Clinically the drug was most valuable in early cases of insanity, but in ordinary acute insanity with extreme rest*lessness and sleeplessness* sulphonal, even in moderate doses, was injurious.—Dr. L. A. WEATHERLY *spoke of the value of* continually renewed air in the induction of sleep as seen in sanatoriums.—Dr. W. JULIUS MICKLE thought that the chief necessity was that narcotics should be given with *brains—i.e.,* that the medical man should make a careful estimate of each particular case before giving any drug. In most cases he would find that the patient did not require a narcotic at all.—Dr. WOODS thought that there were three stages or periods which required *to be taken* into consideration: (1) that before the onset of actual insanity, (2) acute insanity; and (3) chronic insanity. In the first class the judicious employment of sedatives would do a great deal of good. In many cases the dose given was much too large. In cases of insanity with a great deal of motor excitement in which exhaustion rapidly ensued it was necessary to produce sleep by means of sedatives but they should not be continued too long. He laid great stress upon diet and hygienic measures in the third class and feared that sedatives were administered much too freely.—Dr. RAYNER briefly replied. He said that if the injunction to use one's brains were obeyed the practitioner would rarely wish to use a narcotic. The necessity to give a narcotic to avoid alarming the household was quite apart from its curative merits. He agreed with the use of narcotics in cases of bodily pain. In all cases one should try to get rid of the cause of the sleeplessness. Altogether the speakers seemed to be in fair agreement with him.

Dr. T. CLAYE SHAW read a paper entitled, "The Surgical Treatment of Delusional Insanity, based upon its Physiological Study." He said that it was often necessary to argue from effect to cause on account of want of knowledge of the details of the machinery. He proceeded to argue as to what might be supposed to be the physical conditions of a psychic content and from this to draw conclusions as to the probability of there existing a system of "local signature" in the brain in completion of Kulke's theory of specific qualitative colouring. The difficulties under which they at present laboured in treating directly localised lesions in the brain were referred to, and it was suggested that attempts should always be made to trace in which centres they for the most part arose. The importance of localisation was insisted upon and it was argued that if this could be perfected the proper plan was to deal with the disorder surgically, so as to have immediate access to the seat of disturbance—a method attended by little danger and likely to afford valuable results as to progress and ultimate cure.—Dr. HYSLOP referred to his investigations on the same subject and thought that the time was far distant when surgery could be employed with success in the class of cases referred to.—Mr. C. B. LOCKWOOD said the patients he had operated upon for Dr. Claye Shaw were, in his opinion, proper subjects, and where there was a chance of relieving patients from intense pain by surgery it should be done. He gave details of some very successful cases so treated.—Dr. CLAYE SHAW briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Intestinal Resection.—Perforated Gastric Ulcer.—Exhibition of Cases and a Specimen.

A MEETING of this section was held on May 9th, Mr. THOMAS MYLES, the President, being in the chair.

Mr. R. LANE JOYNT read a paper on a Successful Case of Double Resection of the Intestine for Injury. The patient was a youth, aged 16 years, who had been struck in the abdomen by the shaft of a van. He was taken to the Meath Hospital, Dublin, and laparotomy was performed. A portion of the jejunum was found to be torn from its mesentery. The bowel above was severed from the last portion of the duodenum. The rents in the mesentery extended deeply to its roots. The injured bowel, 22 inches in length, was removed, and end-to-end anastomosis was effected by a Murphy's button. The transverse mesocolon was also torn through and only a tube of intestinal mucous membrane over one inch in length stripped of its peritoneal and muscular coats was left connecting the colon. This was excised and a second end-to-end anastomosis was effected with sutures by Cheatle's method. The button was passed on the seventeenth day and recovery was perfect; no disturbance of nutrition had followed. Surgeons were at some disadvantage from want of practice in suturing bowels. The difficulty was to get bowels to suture, for the intestines in the cadaver were so wholly unlike those in the living subject that they were of no use for the purpose. He intended to try the suturing on the carcasses of pigs. The Cheatle suture he found easy to use and capable of being rapidly executed. It had the great advantage that in its application the bowel was not mauled.—The PRESIDENT said that he agreed with Mr. Joynt as to the inadvisability of using a Murphy's button in the operation on the large bowel, especially as one had been used to connect the surgical wound surfaces in the small bowel. The Murphy's button, being liberated earlier in the small intestine, would very probably clude the Murphy's button in the colon. Suturing the bowel had the great advantage of being free from the risk of occlusion; the surgeon was not kept for 17 or 18 days in a state of anxiety waiting for the passing of the button, and with a little practice the bowel could be sutured almost as quickly as the button could be fixed in position. He was much impressed with the fact that the boy was kept for some days without food. Abdominal operations had taught surgeons that food might be safely withheld from patients for some days. In this case delirium supervened but was quickly subdued by the giving of some nourishment.—Mr. L. H. ORMSBY said that when he came to assist Mr. Joynt the case looked hopeless. The operation took two hours to perform. He saw the boy a few days since and found him looking strong and well.—Mr. J. P. DOYLE, Mr. A. J. MCA. BLANEY, Mr. JOHN LENTAIGNE, and Dr. A. R. PARSONS also discussed the case.

Mr. BLANEY read a paper on two cases of Perforated Gastric Ulcer. The first patient, a female, aged 24 years, was operated on 21 hours after the occurrence of perforation. The aperture, situated on the anterior surface near the pylorus, was readily found and sutured. The abdomen was flushed out and was closed without drainage. The patient did well for the first six days; but her temperature then rose and eventually she died from general peritonitis due to the bursting of a localised abscess into the general peritoneal cavity. The second patient, a female, aged 21 years, was operated on 19 hours after the perforation took place. The ulcer was found on the anterior surface near the cardiac end and lesser curvature. There was a great amount of surrounding induration, rendering the application of sutures very difficult. On the eighth day a slight rise of temperature took place; the fever continued, and on the eleventh day the wound was reopened and a large perisplenic abscess was disclosed. This was drained through the ninth intercostal space, a portion of the anterior wound being packed with gauze. The temperature did not subside for a considerable time. Eventually both wounds healed and all stomach symptoms disappeared, but another abscess formed under the scar and it was opened more than two months after the original operation. The patient took raisin tea as it was desirable to avoid the use of proteids in such cases. She was now quite well.

Mr. D. KENNEDY exhibited (1) a case of Excision of the Shoulder for Necrosis of the Humerus and (2) a case of Congenital Dislocation (Sub-spinous) of both Shoulder-joints, with skiagram.

Mr. LENTAIGNE exhibited a case of Tuberculous Disease of the Ankle-joint, with extensive Disease of the Tibia, Astragalus and Os Calcis, cured by raclage. The patient had been already exhibited on March 30th, 1900, and was again exhibited by special request

Mr. W. TAYLOR exhibited a Prostate removed by the suprapubic method.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on May 16th, Dr. W. A. Wills being in the chair.—Dr. James Taylor showed (1) a case of Paroxysmal Hæmoglobinuria in a child who had suffered from Syphilitic Ulceration of the Palate; and (2) a case of Raynaud's Disease in a boy who had lost the Terminal Phalanges of several Fingers and in whose urine oxalates were present in abundance.—Mr. Herbert L. Carre-Smith showed a case of Sporadic Cretinism that had been under treatment for four years with thyroid extract. The mental and physical condition had greatly improved, but a relapse was experienced as soon as the treatment was omitted.—Mr. A. Bruce Roxburgh showed a child with a fatty growth occupying the left side of the perineum and scrotum. The testicle lay in the perineum and a hydrocele of the tunica vaginalis was present. The enlargement was noticed a few months after birth.—Dr. J. Porter Parkinson showed two instances in the same family of a curious congenital depression of the frontal and parietal bones on one side of the cranium. The children, aged respectively 11 months and two years and a quarter, seemed to be intelligent and had never suffered from fits. There were no other evidences of maldevelopment.—Mr. E. W. Clapham alluded to a similar case shown by him before the Clinical Society of London last year.—Mr. Sydney Stephenson showed a case of Keratomalacia in an emaciated infant of the age of seven months who was suffering from tuberculosis, probably of the disseminated variety. The disease already had led to complete destruction of one eye. In the remaining eye the corneal ulceration had healed with the production of a nebula. There had been no ophthalmia neonatorum. The symptoms did not begin until the third month and were those of keratitis and not of conjunctivitis. The latter, indeed, had been absent throughout the case. Clinically, at all events, the gonococcus could therefore be put aside.—Mr. Walter Edmunds exhibited a girl, 11 years of age, suffering from Subluxation of the Left Shoulder-joint. This he regarded as one of the after-effects of epiphysitis with which she was affected as a baby. The arm could be freely moved in any direction except upwards.—Mr. R. Clement Lucas alluded to a somewhat similar case that had been under his care.—Mr. Clapham mentioned another case of the same kind seen in a healthy man who was examined for life assurance.—Mr. H. Betham Robinson showed an example of Springel's Deformity of one shoulder in a girl, 11 years of age. It had been noticed for two months only.—Dr. Travers R. M. Smith alluded to a case shown last year by him at the Polyclinic. Springel's theory was that in utero the arm got behind the back and the shoulder was raised, thus bringing about the deformity.—Dr. James H. Sequeira exhibited a large Sarcomatous Tumour of the Left Supra-renal Body from a girl, aged 11 years, who exhibited the phenomena of "precocious puberty." She had *menstruated for 15 months*, the mammæ were very large, and there was a large growth of hair on the pubes, the chin, and the lip. Secondary deposits were present in the lungs and in the liver.—Mr. Lucas, Dr. F. Parkes Weber, Mr. Robinson, Dr. George Carpenter, and the Chairman discussed the specimen.—Dr. Parkinson showed an Organised Intra-cardiac Thrombus obtained from a boy, aged eight years.—Dr. Douglas Drew exhibited a specimen and sections of an Adeno-myxo-sarcoma of the Testis taken from an Infant.—Dr. C. O. Hawthorne read a note on a case of Arthritis accompanying Ophthalmia Neonatorum which is published at p. 1529 of our present issue.—Mr. Lucas said that it was pleasant to know that a clinical observation made almost in the pre-bacteriological days had been so amply confirmed. His first case was so acute that it appeared as if the joint must suppurate, but as a matter of fact it did not. The peculiarities of the affection were the tendency to recovery without suppuration and the association of suppuration in the conjunctiva.—Mr. Sydney Stephenson remarked that it was a pity that gonococci had not been demonstrated in the eye-discharges from Dr. Hawthorne's patient, but the other circumstances of the case rendered the existence of gonorrhœa quite conclusive. He had personally seen five instances of what might be termed "Lucas's joint disease," and of those cases four of the patients made perfect recoveries under simple treatment. In the fifth case the joint was aspirated and ultimately it became ankylosed.—Dr. Hawthorne, in reply, admitted that the discharge from the eye ought to have been examined for gonococci, but there could be no reasonable doubt as to the diagnosis.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on May 23rd, Dr. Arthur T. Davies, the President, being in the chair.—The President showed: 1. A woman, aged 35 years, with visible Pulsation under the Left Clavicle, with tenderness of the skin over that area. There was a loud systolic noise over the whole chest anteriorly, the loudest being at about the left third costal cartilage. The radial pulses were equal. By the x rays a pulsating mass was seen but with what connected could not be determined. 2. Two men with marked Emphysema of the Lungs who were benefited by wearing Dr Ewart's emphysema jacket. 3. A specimen of Mitral Stenosis with associated Tricuspid Dilatation from a woman, aged 34 years, who died suddenly. 4. A Tuberculous Ulceration of the Epiglottis from a man, aged 36 years.—The President introduced a discussion on Chronic Bronchitis. He advocated the use of the inhalation of a 2 per cent. atomised solution of potassium iodide or similarly ipecacuanha wine. The syrupus picis compositus, U.S.P., with the syrupus pruni virginianæ was chosen, though if fœtid sputa were present the exposure to the fumes of crude creasote in the manner of Dr. T. H. Arnold Chaplin was most useful. The old remedy to relieve the right heart, venesection, might be, at least to some extent, displaced by tartar emetic. For children emetics were undoubtedly very useful. Oxygen, though perhaps not curative, at least induced euthanasia. Climatic treatment was sketched and special praise was given to the Canary Isles, where a variety of climate could be found by going up the mountains.—A general discussion followed.

Reviews and Notices of Books.

On Disorders of Assimilation, Digestion, &c. By Sir LAUDER BRUNTON London: Macmillan and Co., Limited. 1901. Pp. 495. Price 10s. 6d.

THIS book consists of a series of papers on miscellaneous subjects bearing more or less on the question of assimilation and digestion. Most of these papers have been read before learned societies or published in medical journals. In a certain sense this work is a continuation of the author's well-known book on the "Disorders of Digestion," published some few years ago, although in order to avoid confusion between the two books the volume under review has been given an independent and distinguishing title. Comparing this supplementary volume with "Disorders of Digestion" we are forced to the conclusion that the author has not kept his best work for this later publication, and although an apology is offered in the preface for frequent repetition we cannot help thinking that readers who are at all familiar with Sir Lauder Brunton's writings will come to the conclusion that they are justly entitled to an apology of this kind. Two main ideas seem to run through the majority of these essays, one of them is the great importance of rational organo-therapy and the second one has reference to a theory which the author hazarded many years ago when he was working under the direction of Professor W. Kühne—namely, that carbohydrate combustion in the animal system is largely dependent on the presence of a glycolytic ferment in muscular tissues. The influence of enzymes in the physiological processes of the body is undoubtedly great and the more recent discoveries of oxydase and lipase ferments add considerably to their importance, but the underlying and fundamental operations of protoplasm itself and of the nervous system which controls them deserve the equal consideration of any author who discusses the pathology of such diseases as diabetes or the vagaries of an incompetent liver. Nearly one quarter of the book is occupied by a reprint from "The Book of Health" and refers to the influence of stimulants and narcotics on the human organisation. Written in a popular form and bearing a date of nearly 20 years ago, it contributes little to our scientific knowledge of this important subject, and, further, it does not make mention of the more recent and extremely interesting researches on the subject of toxic bodies contained in alcohol which the author himself has carried out. The hereditary effects of alcohol and its relationship to crime, lunacy, and pauperism are now such familiar topics that it is a debateable question whether even Society would learn much that it did not know before by reading this reprint from "The Book of Health." A paper on Bile, Biliousness, and Gall-stones, which was originally read before the North-West London Clinical Society, constitutes one of the most interesting essays of this series. Although subsequently printed in the *Clinical Journal* for January, 1900, it has perhaps not been very extensively read. In this paper appears the curious statement that freshly formed bile is not bitter and that in all probability it only becomes so from absorption of bitter substances formed during digestion. According to the view held by the author it is this bitterness of bile which causes "biliousness." This somewhat expansile term has a more definite meaning to Sir Lauder Brunton than it probably conveys to the mind of most pathologists. Great stress is laid upon the stagnation of bile in the liver as a cause of biliousness and gall-stones, and the want of exercise which mechanically accelerates the flow is held chiefly responsible for the determination of these conditions. Although this explanation has the charm of simplicity it does not explain the association of east winds with so-called biliousness. Nor does it supply a satisfactory explanation of the biliousness of nervous origin or of that connected with railway travelling. Any solution of this problem which does not recognise as pathogenic factors hepatic inadequacy from overwork and nerve exhaustion or hyper-stimulation must necessarily be incomplete if not unsound. The value of flushing out the system with copious draughts of hot water as a prophylactic measure against bile stones and biliary colic will be generally endorsed whether Sir Lauder Brunton's explanation of the *modus operandi* is accepted or rejected. On the subject of constipation and diarrhœa, many useful suggestions are contained in more than one article. Soft food, the consequence of later-day civilisation, is considered to be the principal factor in the etiology of constipation. From the point of view of the general practitioner the volume has many features to recommend it. It is pleasantly written and contains, if we may employ the expression, a large number of useful "tips" in treatment. It is the narrow conception of disease processes and the want of the application of general principles to the particular phases of physiology and pathology which will probably deprive the volume of the enduring appreciation of posterity.

Atlas und Grundriss der Histologie und Mikroskopischen Anatomie des Menschen. (Atlas and Elements of Human Histology and Microscopical Anatomy.) By Dr. J. SOBOTTA. Munich: J. F. Lehmann. 1902. Pp. 247, with 80 coloured plates and 68 illustrations in the text. Price 20 marks.

THIS compact volume, which belongs to a series devoted to the subjects required to be studied by the candidate for medical degrees in Germany, is one of the very best books upon histology which we have seen. It possesses so many merits that we cannot but express this strongly favourable opinion. The text is subsidiary to the illustrations, which is an advantage to those whose business it is to learn the ascertained facts without reference to disputed opinions and to debateable points. The illustrations, with a few necessary exceptions to which we shall revert later, are actual copies of sections which as a rule have been prepared with a view to the present handbook. Being actual copies the author has taken care that they reproduce exactly the very tints used in staining the tissues of which they are representations. Various methods of staining are reproduced in the beautiful plates with absolute fidelity, and to anyone with the slightest experience of microscopical preparations are convincing as representations of actual fact. There is nowhere the slightest trace of any "faking" such as is apt to be seen in drawings of a similar character. Indeed, this pitch of excellence may possibly, in the opinion of some, have been carried a little too far. It is difficult to understand fully the figures of the spleen and of the lymphatic glands. A little judicious explanation in the way of more diagrammatic figures might in these two cases have been of some assistance. With so much that is excellent it is difficult to pick out any one plate or series of plates for especial praise. Among those figures which have struck us as being of particular merit are the drawings of the ovary and the ovarian ovum. The early condition of the corpus luteum is represented with minute fidelity; but perhaps a more highly magnified drawing of the ovum might have been given to illustrate the fact that the neighbouring cells of the follicle do apparently take a share in the nutrition of the ovum in mammals as the corresponding cells unquestionably do in lower vertebrates. The large "glandular" cells of the follicle in the Elasmobranch fishes are, of course, well known. Now Dr. Heape has shown that in the ovum of the mole there are similar prolongations of the follicular cells through the pores of the egg membrane. But in all probability this has not been demonstrated in the case of man, and after all the book is a text-book of human, and not of mammalian, histology.

Nor does the author figure or mention the cell which Professor Schäfer discovered to lie within the ovum, a cell apparently derived from the surrounding follicular layers and corresponding possibly with the cells which penetrate the ovum in the Ascidians. But we may have overlooked some recent proof that these cells are really cells which enter the decaying ovum, as is the case in the eggs of some other and lower vertebrates, during the retrogression of ova that have been ripened but not extruded. It is a little remarkable that Dr. Sobotta does not figure an adult spermatozoon though he gives several figures illustrating the structure of the testis. The illustrations given of the kidney (Fig. 2 on Plate 49 as well as a diagrammatic and explanatory figure) are much to the point in emphasising the probable correctness of the current view that the cavity in which the glomerulus projects is not a part of the kidney tube at all but a segregated part of the body cavity. Dr. Sobotta's drawing shows that the epithelium of this capsule is thin and of a "pavement" character, while the uriniferous tubule begins sharply with columnar epithelium; the columnar region is, of course, at the commencement the equivalent of the funnel of a nephridium in many animals, though it is not ciliated, or perhaps we ought to say, in view of a recent change of opinion, not of a nephridium but of a "cœlomo-duct." It is generally to be inferred from the descriptions of the minute structure of the liver given in many text-books, even if the statement is not actually made, that that alimentary gland is *sui generis* and unlike the other glandular outgrowths of the alimentary canal. This erroneous mode of regarding that organ will be dispelled by a comparison of Fig. 2 on page 22 with Plate 46, Fig. 2. It is rather a pity that the two drawings were not put as nearly side by side as possible. For it is apparent from a glance at both of them that the ductules of the pancreas give off branches running into the actual interior of the pancreas cells just as they have been long known to do in the liver. It happens that in the latter organ these minute ductules form a network, while they do not in the case of the pancreas. But the actual fact of penetration of the cells by microscopic branches of the ultimate ductules occurs in both organs. The study of this fascinating little volume has positively made us long for our remote student days. We can indeed say that in those days there was nothing of such artistic excellence and clearness of explanation to entice the learner into the ways of histology. We distinctly advise every intending student of this branch of anatomy to possess himself of this trustworthy and alluring guide to the mysteries of cell structure.

Plant Relations: a First Book of Botany. Second Edition, revised. Pp. vii.-266. *Plant Structures: a Second Book of Botany.* Pp. vii.-348. Both by JOHN M. COULTER, A.M., Ph.D., Head Professor of Botany, University of Chicago. London: Hirschfeld Brothers. 1902. Price 6*s*. net.

THE first of the above-mentioned books chiefly deals with the ecological relations of plants, or, to use the author's own words, "is dominated by ecology and also contains certain fundamentals of physiology that are naturally suggested." The work does not profess to form a course complete in itself but rather "is intended to serve as a supplement to three far more important factors: (1) the *teacher*, who must amplify and suggest at every point; (2) the *laboratory*, which must bring the pupil face to face with plants and their structures; (3) *field-work*, which must relate the facts observed in the laboratory to their actual place in natur and must bring new facts to notice which can be observed nowhere else" (Preface). Provided these three points are borne in mind by those who use it, the book will not fail to prove of great value and assistance in the study of this most interesting branch of botany. That there is need for such a work there can be no doubt. Unfortunately here in England ecology is very much neglected both by investigators and by teachers. This lack of research is the more to be regretted since much could be done by many who for various reasons are unable to work on the same lines of investigation which are more generally followed by many botanists. The volume is illustrated by over 200 figures, a number of which have been obtained from Kerner's "Natural History of Plants" and Schimper's "Pflanzengeographie," now being translated, we understand, for the use of English students.

The second book—Plant Structures—deals essentially with the morphology of the main groups of the vegetable kingdom. The ground covered may appear to be too wide for the elementary reader, but it must be remembered that it is not intended by the author that the whole of the contents should be used for laboratory exercises, but to form a means of coördination and "to develop some philosophical conception of the plant kingdom." Although the work is quite good on the whole there are a few points to which exception must be taken.

In Chapter 12 the Fertilisation of Angiosperms is described. The process outlined is that which was taught up to 1899—that is to say, no mention is made of the important discoveries of Nawaschin, Guignard, and other observers on the "double-fertilisation" of certain flowering plants, both Monocotyledons and Dicotyledons. Hence we find that the endosperm is compared to, and said to be homologous with, the prothallus of Gymnosperms. This theory, though still held by some, is not by any means considered to be true by all. Again, on p. 291 it is stated that "the large club-mosses and *Isoetes* usually have an apical group of meristem cells, as among the seed plants." As regards *Isoetes* there is some evidence which points to the fact that the stem-apex may grow by means of a single apical cell, as Hofmeister supposed 50 years ago. While dealing with *Isoetes* attention also may be drawn to another statement which might be improved upon. We find that on p. 292 it is stated that in the plant in question "the vascular bundles may be said to be collateral." It is only fair to point out, however, that some of the above points objected to may be due to the fact that although the volume is dated 1902, it does not appear to have been revised since the time of its first publication in 1899. The work is illustrated by 289 excellent figures and will doubtless prove of much use.

A Text-book of Medical Jurisprudence, Toxicology, and Public Health. By JOHN GLAISTER, M.D. Glasg., D.P.H. Camb., F.R.S. Edin., Professor of Forensic Medicine and Public Health in the University of Glasgow, &c. With 238 illustrations. Edinburgh: E. and S. Livingstone. 1902. Pp. 820. Price 15s.

IN this work the plan has been adopted of combining in a single text-book the subjects of medical jurisprudence, toxicology, and public health. We consider this method a good one both for practitioners and students. All three subjects imply relationships subsisting between the medical man and the State and at most of the qualifying examining boards the subjects are now conjoined for examining purposes. Dr. Glaister modestly remarks that on none of the subjects does the volume pretend to be exhaustive. He has, however, produced an excellent manual, fully carrying out all that is claimed for it—that is to say, that in its pages will be found a consideration of the most important problems in each of the departments of which it treats.

The experience gained by the author in the field of medico-legal work and practice and in the teaching of the subjects comprised in the book for many years has convinced him that the kind of book most needed by practitioners and students alike is one which combines the exposition of principles with practical details. On this point we entirely agree with him. Unless interspersed with illustrative cases a text-book on forensic medicine is found to be somewhat uninteresting reading. If, however, certain cases are selected and are then compared with theoretical considerations valuable lessons are acquired. Not only will the student more readily grasp the principles of the science, but he will gain an insight into the manner in which medico-legal cases should be conducted and will be warned against the many pitfalls into which an inexperienced medical witness or officer of health may fall.

The book is divided into three sections. Section I. deals with Medical Jurisprudence. The earlier chapters describe legal criminal procedure in England, Scotland, and Ireland and the methods which should be adopted by the expert witness when giving evidence in court. The vexed question of professional secrecy is ably discussed. It is interesting to note that medical men in certain parts of the world are in different positions in this matter. In England a medical witness must disclose, when a judge so rules, any secret information of which he may be possessor by virtue of his professional relationship to a party in the case. In New Zealand, on the other hand, all communications made to a physician or surgeon in his professional character by any of his patients are held to be privileged and are not admissible in evidence in any civil or criminal proceedings, except with the express consent of the person who is alleged to have made such communication; a similar rule prevails in certain American States.

The chapter on Personal Identity is also well arranged. Full accounts are given of the methods employed in the identification of prisoners by the Bertillon system and by the finger-print systems of Galton and Henry. The chapter on the Medico-legal Forms of Death—namely, drowning, suffocation, hanging, strangulation, and throttling—contains a full account of the appearances which may be present in such circumstances, together with the deductions which may be drawn from them. Other chapters deal with Death by Lightning and Electricity, Death by Cold and Exposure, Wounds in their Medico-legal Bearings, and the Examination of Blood-stains. The medico-legal relations of the sexual functions, rape, and infanticide are also duly discussed.

A useful and instructive chapter is one on the Differential Diagnosis of States of Insensibility, a subject which frequently comes under the notice of the resident medical officers of the general hospitals and which occasionally presents problems of the greatest difficulty. The chief points are described upon which an opinion may be formed, but the main object of the chapter is to warn the young practitioner against coming to a too hasty conclusion. The instruction given to house surgeons and house physicians never to send away an unconscious patient is a good and sound one and should never be departed from.

Section II. is concerned with Toxicology and an account is given of the symptoms, mode of detection, and treatment in cases of poisoning by organic and inorganic substances. The directions given for chemical analysis are unusually full and complete.

Section III. is headed "Public Health." The high standard of description and reasoning exhibited in the previous parts of the book is fully maintained in this section. The chapter on Air and Ventilation is particularly worthy of attention and the principal appliances which are adopted for the ventilation of closed spaces, large and small, are described in detail. Especial attention is paid to the mode of testing practically schemes of ventilation, and the information thus given should prove of considerable value to medical officers of health and to those practitioners who are charged with the supervision of workshops and factories. The subject of house drainage is likewise dealt with at length, as are also those of sewage disposal and methods of sewage destruction.

Some interesting chapters are added which are not always to be found in a text-book of this nature. Chapter 9 is headed "Preventable Diseases." Brief accounts are given of the mode of spread of the infectious diseases, particular attention being drawn to yellow fever, plague, and malaria. Then follow chapters on Methods of Prevention of Infectious Diseases and Modes of Disinfection of Individuals, Clothing, and Rooms. The sanitary law relating to infective diseases is also explained. Chapter 13 is concerned with the Construction and Requirements of Isolation Hospitals and the final chapter deals with the Effects of Occupation on Health and the Duties of Medical Practitioners regarding Industrial Poisoning.

Taking this work as a whole we can unhesitatingly pronounce it to be one of the best text-books dealing with medical jurisprudence, toxicology, and public health which we have met with. It is well written throughout, the information contained in it is full and accurate without being redundant, and the illustrations are appropriate and well executed. We can cordially recommend it to medical practitioners and students and also to members of the legal profession who will find therein a useful guide in a class of cases which are often perplexing to the legal mind.

LIBRARY TABLE.

Contributions from the William Pepper Laboratory of Clinical Medicine, University of Pennsylvania. No. 2. Philadelphia. 1901.—This volume is made up of reprints of a number of papers by various observers. Dr. W. G. Spiller is responsible for seven articles on subjects connected with diseases of the nervous system, including the following: "The Pathological Changes in the Neurone in Nervous Diseases," "A Case with the Symptoms of Cerebro-spinal Meningitis, with Intense and Cerebral Alteration of the Nerve-cell Bodies, but with little evidence of Inflammation;" and (in conjunction with Dr. W. E. Robertson and Dr. W. S. Wadsworth) "Cerebellar Lesions without Cerebellar Symptoms." An interesting communication is that by Dr. A. Stengel and Dr. C. Y. White on "The Blood in Infancy and Childhood." Another paper well worthy of notice is by Dr. C. Y. White and Dr. William Pepper on "Granular Degeneration of the Erythrocyte." The observers studied more especially the granular degeneration found in the erythrocytes of lead workers and were able to demonstrate the granules very early in cases under the influence of lead salts before subjective or other objective symptoms could be detected. Dr. White and Dr. Pepper believe these granules to be a true degeneration of the erythrocyte and to have no relation to nuclear fragmentation or to polychromatophilia.

De la Conjunctivite Granuleuse. Par le Dr. Z. Hourmouziadès, Aide de Clinique Ophtalmologique à l'Hospice National des Quinze-Vingts. Avec préface par le Dr. A. Trousseau. Paris: Société d'Éditions Scientifiques. 1902. Pp. 190. Prix 4 francs.—The conjunctiva is the most extensive, the most superficial, and the most easily examined of the membranes of the eye. Yet the diseases to which it is liable from its exposed position are so diverse that with all the aid that the microscope can afford there is by no means complete uniformity of opinion in regard to the etiology, diagnosis, symptomatology, and treatment of certain forms that to the casual observer seem identical. The truth is that the conjunctival sacs are favourable to the retention of various kinds of low organisms which find in the warmth and moisture of these folds of membrane conditions favourable to their multiplication; suppuration is then easily established and, when abundant, masks the primary disease, and hence the affections named chronic catarrh, chronic purulent ophthalmia, military or Egyptian ophthalmia, granular lids, follicular conjunctivitis, and trachoma have been by different authorities classed together as forms of the same disease. The author of the present little *brochure* regards military ophthalmia and trachoma or granular conjunctivitis as two quite distinct affections and considers trachoma as invariably chronic. His inquiries show that in 1888 there were in the Prussian army two cases of trachoma in every 1000 soldiers and in the Austrian army at about the same date there was a ratio of 8 per 1000. The pathological conditions present in trachoma are well described and illustrated. He quotes in full the description of Larrey in regard to military ophthalmia as he observed it in Egypt, and the account given in Mackenzie's treatise of the outbreak of contagious ophthalmia on board the slave ship *Rôdeur* and shows that these were examples of contagious ophthalmia. He gives as the consequences of trachoma symblepharon posterior, xerosis, entropion, ectropion and trichiasis, blepharitis, pannus, ulcers, abscess, and opacities of the cornea, and, which is not generally admitted, secondary glaucoma. In regard to the etiology of the disease he has no doubt that it is contagious, the contagium being a special but not yet isolated microbe. A chapter is devoted to the geography of the disease in which it is shown to be very widely distributed, diminishing in frequency from the south towards the north. In the section on the Treatment of Trachoma reliance is placed by the author on the internal administration of arsenic, quinine, cod-liver oil, iodide of iron, glycerophosphate of lime, and citrate or malate of iron, and the topical action of nitrate of silver, sulphate of copper, petroleum, corrosive sublimate solutions of various strengths, tannic acid, alum, subacetate of lead, chloride and sulphate of zinc, chromic acid, protargol, binoxide of mercury, tincture of iodine, iodoform, boric acid, mercury cyanide, salicylic acid, pyoctanine and ichthyol—an array of drugs that in themselves sufficiently attest the obstinacy of the disease, leaving out of the question the surgical measures that have been often fruitlessly employed—such, for example, as the thermo-cautery, scarification, *brossage*, extirpation of the superior sac, and other proceedings. Though the treatise is small it contains much information and may be read with advantage by all who are working in ophthalmic wards or hospitals.

Four Epochs of Woman's Life: A Study in Hygiene. By Anna M. Galbraith, M.D., Fellow of the New York Academy of Medicine. With an introductory note by John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania. London and Philadelphia: W. B. Saunders and Co. 12mo., pp. 200. 1902. Price 5*s.* net.—In this work the author discusses many questions of interest to mothers and their daughters. She considers the four epochs of a woman's life as maidenhood, marriage, maternity, and the menopause. Under the first heading a short account is given of the anatomy and physiology of the female generative organs and of some of the anomalies of menstruation. The second part deals with such matters as the marriage question mainly from the medical point of view and the ethics of married life. In the section on maternity some useful information is given as to the care of the mother during her pregnancy, confinement, and the lying-in period, and the care of the newly-born infant. Lastly, the troubles likely to assail a woman at the menopause are considered and some hints are given for home treatment. The book is interestingly written and should prove of value to women.

secrecy must be strictly observed by every member of a hospital staff. The law is quite plain on the matter, recent decisions of the Court of Cassation having laid down the principle that professional secrecy is never to be violated and that not even in a court of justice can any statement involving such violation be accepted as evidence. The circumstances leading up to Dr. Bonnaire's question were cases of criminal abortion, many of which come under his care. He was anxious to know whether after an admission on the part of the woman herself that such an operation had been performed he, as the *accoucheur* in charge, was justified in informing the authorities, so that the accused might be arrested and such nefarious practices put a stop to. The answer, however, was in the negative.

The Analysis of Urine and the Illegal Practice of Medicine.

The Tenth Chamber of the Correctional Tribunal has just given judgment in a case involving the illegal practice of medicine. The case was that of a pharmaceutical chemist who was accustomed to make analyses of urines. Some patients were sent to him for the purpose by physicians and some came of their own accord. So far there was nothing wrong in his action, for every patient has the right to have his urine examined by whomsoever he wishes. But the pharmaceutical chemist did not stop there, but when he sent the result of his analysis he also formulated a diagnosis and what he considered to be appropriate treatment. He was accordingly prosecuted and the tribunal decided that to make a diagnosis and to prescribe treatment did not fall within the normal province of an analyser of urines and that such conduct trespassed on the preserves of the medical man. The accused was convicted of illegal practice and had to pay 50 francs fine and 50 francs damages to the syndicate of medical men.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Preventive Measures against Small-pox over a Large Area.

THE prevalence of small-pox in the United States is unprecedented and it has led to extraordinary measures to control its spread. The city of Chicago as a centre of trade and travel has an area of 600,000 square miles in 10 States and the remotest boundaries of this area are within a few hours' travel of that city. Between Dec. 28th, 1900, and Jan. 24th, 1901, there were 1070 cases of small-pox reported in that territory, while during the same period ending Jan. 24th, 1902, there were 10,000 cases reported, an increase of 911 per cent. To meet this emergency the Chicago health authorities held a conference with the representatives of the railroads entering the city and submitted a plan of procedure which the railroad officials accepted and will aid in enforcing. The plan contemplates a wholesale vaccination and re-vaccination in every infected locality. The details are as follows. The work along each line of railway will be under the direct charge of the medical director or chief surgeon of the company and a central office will be opened and maintained in the city for the receipt of reports, requisitions, &c., from all persons engaged in the campaign. Competent vaccinators and supplies of pure lymph thoroughly tested will be furnished gratis in all proper cases. Special attention will be paid to the condition of employés in manufacturing establishments, particularly those of textile fabrics, and the railway officials will set the example by still more rigorously making recent vaccination a condition of further employment. Provision is also made for the maintenance of suitable isolation hospitals where necessary and for the thorough disinfection of all premises and their belongings where small-pox has occurred. The officers of the railroads engage to maintain a rigid inspection of all persons wishing to travel from infected localities and to refuse to carry those who do not comply with the requirements.

State Quarantine against Consumptive Persons.

There has been much agitation over the reported action of certain States, reputed to have climates favourable to persons suffering from pulmonary tuberculosis, favouring quarantines against persons suffering from consumption. This is especially true of Colorado, the resort of the larger number of this class. Such action of State officials is now authoritatively denied by past and present officers of the State Board of Health and of the State Medical Society. In a circular these deny (1) that any member of the Colorado State Board of Health ever proposed to prevent tuberculous persons from entering the State; (2) that any member of the legislative or executive branch of the State of Colorado ever suggested such action; (3) that there is any law to that effect on the statute-book; (4) that there is any ordinance of any city or town to that effect; and (5) th assert that, on the contrary, the Colorado State Board of Health issued in 1900 a circular, stating that the climate the State had saved the lives of many who had come ear could not be doubted and that there was no need quarantine against consumptive persons, such a course bein both unnecessary and impracticable. They added the following in conclusion: "Doubtless, many persons with advanced tuberculosis should not be sent here, but for those who can be benefited by coming Colorado should have nothing but a warm welcome."

Responsibility for the Deaths from Tetanus following the Use of Diphtheria Antitoxin.

The fact that 13 deaths occurred in St. Louis from tetanus after the injection of diphtheria antitoxin has been noticed in a previous letter. The public alarm at the possibility of such an accident has discredited the use of antitoxin obtained from laboratories under municipal management. The finding of the court appointed by the Board of Health to fix the responsibility for the accident is as follows: "1. The diphtheria antitoxin heretofore issued by the city was prepared, bottled, and distributed by and under the supervision of Dr. Amand Ravoid who was employed by the Health Commissioner, with the approval of the Board of Health, in 1894, as consulting bacteriologist and to have charge of the preparation and distribution of diphtheria antitoxin, and that he was responsible for the quality of material so prepared and distributed. 2. That horse kept by the city under the supervision of Dr. Ravoid as a producer of diphtheria antitoxin serum was bled by him on Sept. 29th, 1901, and on Oct. 2nd was found to have tetanus and was killed. 3. From Dr. Ravoid's testimony the poisonous character of the serum from this bleeding of Sept. 29th was known to him but he failed to cause the serum to be destroyed. 4. That owing to this inexcusable negligence the poisonous serum was, in part, bottled and issued to physicians between Oct. 10th and 23rd with deplorable results." The recommendation is to the effect that Dr Ravoid be discharged from the service of the Health Department and that the city do not hereafter manufacture diphtheria antitoxin.

Dispensing with the Term "Insane."

The Butler Hospital for the Insane at Providence, Rhode Island, has dropped the word "insane" from its title and from all its letter-heads and bills, leaving only the term "Butler Hospital." The object of this action is to remove from its inmates the stigma which attaches to their admission to an institution devoted to the care and treatment of the insane. The superintendent, Dr. Blumer, remarks: "Many of our patients come to us needing treatment merely and destined soon to leave restored to perfect health. It is almost a wrong to these patients that it should be said and remembered of them that they have been insane or the inmates of an 'insane asylum' or a 'hospital for the insane.'" This action of the managers of that old and reputable institution is destined to be followed by other similar institutions and the day is not distant when the meaningless terms "insane" and "insanity" will be abolished in this country.

Military Hygiene to be Taught at West Point.

The Secretary of War has directed the academic faculty at West Point to consider and to prepare a course of study to be given to the cadets which shall include full instruction in military hygiene. This addition is strongly favoured by the superintendent and other progressive line officers who believe that the object lessons of the war with Spain should not be disregarded and that the scientific and technical training of the cadets should, if necessary, be cut down so as to permit of their proper instruction in the care of troops. The superintendent is impressed thoroughly with the belief that military efficiency depends upon the attainment of four great essentials—viz., suitable armament, proper food, efficient transportation service, and careful sanitary government; he therefore favours a course of instruction in practical military hygiene to the cadets extending over not less than 30 hours in each academic year.

An American Hospital in Paris.

The American residents in Paris have long felt the need

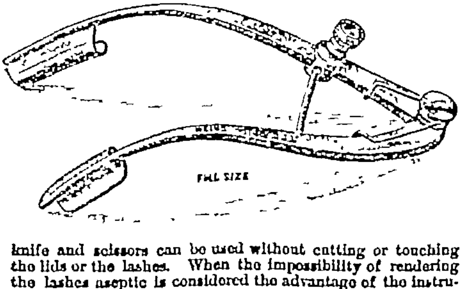
An Introduction to Physiology. By WILLIAM TOWNSEND PORTER, M.D., Associate Professor of Physiology in the Harvard Medical School. Part IV., Physiological Optics. Cambridge, Mass.: University Press. 1902. Pp. 99. Price 2s.—This little work is intended to teach the student how by means of a few lenses and some easily made apparatus he can perform physical experiments that will enable him to understand the principles of refraction and reflection of light. The apparatus, of which a drawing is given, consists of a small lantern containing an electric light and having an opening at one side into which a tube containing three lenses and a diaphragm are fixed. The light emerging from this chamber, owing to the disposition of the lenses, is composed of parallel rays and enters an orifice in the side of an adjoining optical box. The course of the rays in this chamber is rendered apparent by burning some Japanese incense. The position of the principal focus and of the conjugate foci, the laws of reflection and refraction, can with a little ingenuity on the part of the student be easily demonstrated. Having mastered these fundamental facts the phenomena of refraction in the eye are discussed and a good account of the mechanism of accommodation as explained by Helmholtz is given. The views of Tscherning are not mentioned. Sections are, of course, devoted to the subjects of myopia, hypermetropia, and astigmatism. In small compass the author has compressed a large amount of useful information.

ERRATUM.—In reply to a correspondent we inadvertently stated in THE LANCET of April 26th, p. 1224, that the price of "The Operations of Surgery," by W. H. A. Jacobson and F. J. Steward, was 34s. This was quite true as regards the third edition but the price of the new (fourth) edition is £2 2s.

New Inventions.

AN EYE SPECULUM.

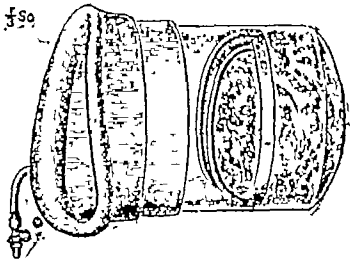
THE accompanying drawing illustrates a modification in Clark's speculum which has been made for me by Messrs. Weiss. It consists in the eyepieces being solid, to keep the lashes out of the field of operation during the extraction of cataract, iridectomies, discission of capsule, and similar operations. This end it fulfils perfectly, and although the increase in the bulk of the eyepieces limits slightly the width of the palpebral opening, still the surgeon soon accustoms himself to this trifling inconvenience, which is more than compensated for by the free way in which both knife and scissors can be used without cutting or touching the lids or the lashes. When the impossibility of rendering the lashes aseptic is considered the advantage of the instrument, which keeps them away from the wound, will be recognised by everyone who does not cut off the lashes before operating.

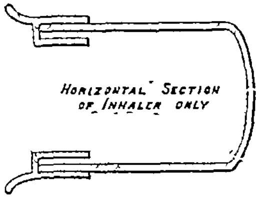


Cavendish-square, W. WILLIAM LANG.

A NEW ANÆSTHETIC INHALER.

WHILST administering the A.C.E. anæsthetic with the celluloid cap and sponge inhaler, my attention has been drawn on various occasions to the two imperfections in this method of administration. These are: first, in prolonged operations the sponge becomes saturated with the anæsthetic with the result that the excess of liquid and exhaled moisture flows down the inner surface of the inhaler on to the patient's face, causing blistering or cutaneous inflammation, which though slight in character is not infrequently irritating and troublesome; secondly, the sponge, unless fitting accurately and rather tightly to the concavity of the inhaler, tends to fall, especially when saturated with the anæsthetic, on to the patient's face.





To obviate these two possibilities Messrs. Down Brothers made, according to my instructions, the celluloid inhaler here shown and described. For the prevention of blistering of the face I have devised the detachable face-piece with an inner lip, leaving a space between it and the inner surface of the inhaler of sufficient depth to contain any excess of moisture which flows down the inner surface. This face-piece can be detached at pleasure and any excess of liquid in the space between the two lips can be shaken out over a towel. With regard to the possibility of the sponge falling on to the patient's face, this is prevented efficiently by the light metal spring with cross-bars fitting the inner circumference of the inhaler. After giving the inhaler a thorough trial I am confident that these two simple additions are effectual and add greatly to the comfort of the administration. I must draw special attention to the importance of removing the face-piece as soon as the administration is over as the action of the anæsthetic is liable after a time to cause adherence to the inhaler. A. WARING, M.B. Lond.

Nottingham.

COLCHESTER MEDICAL SOCIETY.—The spring meeting of this society was held at the Cups Hotel, Colchester, on May 20th. In the absence of the President (Mr. J. Taylor of Earl's Colne) Mr. Alderman H. Laver, J.P., took the chair. 18 members sat down to dinner and afterwards the general meeting was held. Dr. E. Chichester read a paper on Methods of Detecting the Diphtheria Bacillus, with microscopical demonstrations. Dr. Sinclair read a paper on Albuminuric Retinitis in Pregnancy. The Secretary (Dr. B. H. Nicholson) showed the following: (1) A case of Phelps's Operation for Talipes, with complete cure after four years; (2) Bow-legs, Osteotomy of the Tibia and the Fibula with x-ray photographs; and (3) a case of Excision of the Tongue by Whitehead's Method with Ligature of the Lingual Artery.

THE LANCET.

LONDON: SATURDAY, MAY 31, 1902.

Army Medical Efficiency.

THE Secretary of State for War and Sir FREDERICK TREVES in the course of their speeches at the late annual gathering of officers of the volunteer forces who have served in the South African war made some allusions to the Army Medical Service which are not without interest at the present time seeing that the competitive examination for admission into the Royal Army Medical Corps in July next is the first examination which will take place under the terms of the new Royal Warrant. The probable results of that examination have given rise to a good deal of speculation and curiosity. Meanwhile, Sir F. TREVES, in speaking about "The Imperial Forces," alluded in eulogistic terms to the way in which Mr. BRODRICK had set about doing the hard and responsible work which it had fallen to his lot to encounter. Sir F. TREVES remarked that as to the Army Medical Service it was the Secretary for War's avowed object to obtain the best that could be provided. This afforded Mr. BRODRICK an opportunity of recognising and very graciously thanking Sir F. TREVES and his colleagues not only for their great services in the field during the most arduous portion of the campaign but also for the valuable aid which Sir F. TREVES and other distinguished members of the medical profession had subsequently rendered by their unremunerated labours in the reorganisation of the Army Medical Department.

Speaking of the amendments and changes which had been found necessary in the Army Medical Service "owing to the greatness of this war," Mr. BRODRICK expressed his confidence in the success of the task that had been committed to them because of their having had at their back for the first time the heads of the civil medical profession, who he hoped in future would work hand in hand with the Royal Army Medical Corps to the immense advantage of the British soldier and of the nation. In saying this the War Minister is expressing a view which we have always held. The public medical services and the great body of the civil profession are bound up with one another; their interests and relations are mutual and reciprocal, and the heads of the civil profession in reality constitute the only special scientific jury that can properly estimate and judge of the value or otherwise of the work done by the public medical services. So long as these services are recruited from the medical universities and schools of this country it is obviously necessary that the terms and conditions held out by the Government should be such as to commend themselves in the main to the great body of the profession. Speaking broadly, what is best for the public is best also for the medical service and the profession. A medical department [illegible] scientific, technical, and specialised branch of service, and the nation has a right to expect that its members shall be of good quality, well trained, and up to date in their acquirements and practice. Efficiency in the army is now the cry, and if the alleged disclosures in the forthcoming report of the Committee on the Education and Training of Army Officers be well founded there would seem to be plenty of room for radical changes and reform in other directions than the Army Medical Department. To say that what is wanted is a really efficient medical service is no doubt merely to state a platitude but the means to secure it are nevertheless apt to be lost sight of. It means money for one thing, but it means other things besides money.

Taken as a whole the new Warrant is, as we have said, a good Warrant; it contains a number of new and excellent points and goes a long way towards securing efficiency. Increased facilities for professional study will call for an increase of the medical establishment by which it is to be hoped that the amount of foreign service on the part of medical officers will be lessened. We have no doubt about the sincerity of Mr. BRODRICK'S intentions and efforts, as Sir F. TREVES assures us is the case, to provide the army and the nation with the best medical service. There is an important matter, however, to which, although we have frequently touched upon it already, we must again refer. It is as to the position and rates of pay of medical officers whilst serving in India under the Indian Government. Candidates for commissions in the Royal Army Medical Corps are, it seems to us, entitled to have some definite information on this head and to know also whether it is proposed to take any steps to lessen the undue amount of foreign service which medical officers have had to perform for some years past. We venture to suggest that it would be very useful and opportune if Mr. BRODRICK were to seize an early occasion for enlightening us on these points.

Hæmatology.

WE have on several occasions drawn attention to the advances which have been made of late in our knowledge of the pathology of the blood. The results which have been published by numerous observers go to show that valuable clinical information may be obtained by systematic examination of the blood. The technique required is gradually being simplified and the more recent methods are neither elaborate nor difficult to learn. The time required for counting the blood-corpuscles may in the early endeavours be considered rather long, but with practice will come celerity.

The rapid growth and development of this particular branch of medical science have caused it to be distinguished by a separate name—"hæmatology"—and in conjunction with the investigations that have been made many terms hitherto little known have now come into common use and several new ones have been introduced. Thus the red blood corpuscles are denominated "erythrocytes," whilst according to their size and nuclear characteristics they are designated as normoblasts, megaloblasts, and microblasts, whilst certain intermediate forms are known as mesoblasts. The white blood corpuscles are, of course, now referred to as "leucocytes." It has been shown, however, that no less than six distinct varieties of leucocytes may be recognised in the healthy blood of an adult. They occur in varying numbers and percentages under different physiological and pathological influences, and an accurate knowledge of their appearances and the conditions under which they are seen or are absent will lend considerable aid in many cases of doubtful diagnosis. The leucocytes are, under certain circumstances, increased in number, yielding the condition known as leucocytosis. This phenomenon is being investigated by many observers and if a complete knowledge of its mode of production has not yet been arrived at it is not for want of much intelligent observation and work. Leucocytosis has been shown to exist under both physiological and pathological influences. Under the former are included leucocytosis of digestion, of pregnancy, and of parturition. A transient increase in the number of leucocytes of the blood drawn from a peripheral vessel, and not involving a disturbance of the normal ratio between the different forms of cells, is produced by active local or general muscular exercise, by brief exposure to atmospheric cold, and by the application of electricity and of massage. Dry or moist heat, if long applied, also increases the number of leucocytes. Terminal or pre-agonal leucocytosis is a term which has been given to the increase in the number of white cells which has been observed shortly before death. Under the term "pathological leucocytosis" a number of conditions are included—inflammatory and infectious leucocytosis, post-hæmorrhagic leucocytosis, toxic leucocytosis, and the leucocytosis associated with malignant disease. The estimation of the percentage of hæmoglobin of the blood also affords useful information, especially in the diagnosis of pernicious anæmia. Other processes have been introduced, but at present most of these are only in the experimental stage and their clinical indications have not been accurately determined. Amongst them we may mention the estimation of the relative volumes of corpuscles and plasma, estimation of the specific gravity of the blood and of its alkalinity, determination of the rapidity of coagulation, and the counting of the blood-plaques. The other procedures which are better known, and which we need only mention to complete the list of processes to be resorted to in a complete examination of the blood are simple microscopic examination of the fresh blood, bacteriological examination, determination of the serum reaction, and spectroscopical examination.

It will thus be seen that hæmatology is rich in results that have already been achieved and also in possibilities that future research may develop. A practitioner wishing to keep abreast with modern methods of clinical examination cannot afford to disregard the work which has already been done. The indications yielded by the observation of changes which occur in the blood under varying conditions have now a definite value. They may be divided into two main classes—namely, phenomena which are pathognomonic of certain diseases; and auxiliary data, which may prove most helpful in establishing the precise nature of a disease when considered in connexion with other clinical manifestations. Of the first class, the most typical examples are afforded by the results of hæmatology in connexion with leukæmia, malarial fevers, and filariasis. In the second class we may mention as instances in which an examination of the blood is almost essential for diagnosis, Hodgkin's disease, splenic anæmia, and secondary anæmias dependent upon various causes. With regard to the last-named, the blood has been shown to give valuable information in the diagnosis of appendicitis, malignant disease, enteric fever, sepsis, and diabetes, and in many cases prognostic indications are also yielded. In hæmatology we have a factor in clinical diagnosis which is likely to take a prominent position in the near future. We have referred only to the principal facts which have been established but there are many minor ones which may presently be considerably elaborated. Students of the present day, therefore, will do well to familiarise themselves with the methods involved in the examination of the blood, for a knowledge of hæmatology bids fair to be of great value in practice.

Cancer Research.

A MEETING of the directors of the Royal Infirmary, Dundee, was held on Thursday, May 8th, at which a letter was read from Mr. J. K. CAIRD intimating that he was prepared to give the munificent sum of £18,500 to build a new hospital exclusively for cancer patients. The fact was briefly announced at the time by one of our Scottish correspondents. The building, we understand, will contain three wards for males and three wards for females of from 16 to 20 beds each, also one ward of six beds and 12 rooms of one bed each for paying patients. Provision will be made for six dining-rooms for convalescents, six kitchens, six rooms for patients' clothes, six pantries, and six store-rooms, besides bathrooms and sanitary accommodation. The upper floor will have about 26 bedrooms for nurses, with three sitting-rooms, a box-room, and a lavatory. The tentative plans for the new hospital, which it is proposed to erect behind the infirmary, show a design for a building in two pavilions each complete in itself, so that one half can at any time be used for other than cancer patients in relief of the present infirmary. Mr. CAIRD proposes that "one of the wards which may not at first be occupied might be fitted as a laboratory for original work in the investigation of the disease and its cure, for which an additional sum of £1000 each year for five years will be guaranteed." The directors at once decided to avail themselves of Mr. CAIRD'S generosity, to build the new hospital according to the donor's plans, and to take upon themselves the responsibility of furniture and maintenance.

Mr. CAIRD by his generosity displays not for the first time a desire to lighten the sick man's burden, a desire which cannot be held in too high esteem. His philanthropy could not be directed towards a more worthy and deserving purpose than the relief of patients suffering from cancer, while his wish to further scientific research shows that he appreciates the value of what has been done of late years in our physiological and pathological laboratories. If we venture to criticise the conditions of the second portion of his gift to his native town it is with full appreciation of the excellence of his motives. We may perhaps suggest, however, that at the present time Mr. CAIRD'S intentions to benefit the victims of cancer would be more speedily fulfilled if the £5000 to be spent on research work were handed over to the committee appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England for the systematic study of this terrible disease. In a leading article in THE LANCET we recently commented on the general character of the scheme proposed by the Royal Colleges to be set in motion for the investigation of cancer. We criticised certain points in the scheme that we thought might have been bettered, but our criticism was directed to detail. Any well-organised attempt to protect our population from the terrible scourge of malignant disease must in its main object command our approbation. The Royal Colleges need funds in order to carry out the proposed measures of research and Mr. CAIRD'S munificence to Dundee will, we hope, encourage other wealthy philanthropists to dower the efforts of scientific research in London.

We cannot help wishing that it had occurred to Mr. CAIRD'S generous mind to adopt this course. This we say with no desire to detract from the merits of his admirable action or to deprive Dundee of any of the fruits of her open-handed citizen's generosity. We congratulate Dundee upon possessing Mr. CAIRD and Mr. CAIRD upon his resolute intention to benefit his sick neighbours in a thoroughly practical manner, but we have some doubts whether the course that he has adopted in subsidising a school of special research in Dundee is the one that will best serve his ultimate purpose. The prevention of cancer is a pressing matter and if Mr. CAIRD'S idea is carried out it will involve a delay of perhaps two years before the new efforts of research will be initiated at Dundee. The buildings are not ready and when they are erected and equipped officers with sufficient experience will have to be found and appointed to carry out the investigations and to use their best endeavours to get into touch with the other workers in the same field. Isolation in scientific research almost inevitably means that much work is done that is unnecessary, because it is done over ground that has already been thoroughly tilled by others. The supervision of the investigations accomplished by various observers by a competent central committee obviates such repetition.

Annotations.

"Ne quid nimis."

A NOVEL WITH A PURPOSE.

RATHER more than three years ago Mr. Rider Haggard entered into honourable competition with Ibsen and Zola by attempting to cure with a novel the deafness and blindness of those for whom blue-books and statistics are vain things fondly invented. In "Dr. Therne" he wrote a didactic treatise which is also an excellent story and there is no doubt that in so doing he served admirably the cause of public health by his vigorous advocacy of vaccination. We have received copies of an interesting correspondence which has taken place between the well-known author and a convert whom he has made. Mr. George J. Battle of Rushden, in his letter to Mr. Haggard, states that "Dr. Therne" has controverted theories concerning vaccination which he has held for 20 years. "At Wellingborough," he says, "in 1898 I was fined for non-compliance with the Vaccination Act and I have since obtained exemption certificates for my three children under the conscientious objectors' clause in the Act of 1898. Your 'Dr. Therne' has made me think that non-compliance with the Vaccination Act is the worst course to take and I shall not only have my children vaccinated but shall submit to the operation myself." Mr. Rider Haggard, in replying to the letter, after saying that he wrote the book out of the fulness of his faith in vaccination, tells the following story: "A week or so ago the local papers reported an outbreak of small-pox at Ipswich. From the report it would seem that the father of the family had the elder children vaccinated. He then became an anti-vaccinist, with the result that the younger children were not thus protected. Small-pox got amongst the family and (according to the report) the unvaccinated children were all stricken down, while so far the vaccinated had remained immune." Stories equally convincing might be multiplied and it is not infrequent for our readers to ask us why we do not lay stress upon such cases. As a matter of fact such occurrences told in our columns have no particular effect, as our pages are read by an audience already in no doubt as to the benefit of vaccination. But when a popular novelist like Mr. Haggard, who has also shown himself to be a serious and responsible politician, narrates them in the columns of a lay paper they have great weight. We congratulate Mr. Battle on having the pluck to announce a change of mind. We are often invited to do honour to the courage of persons who remain true to their convictions in the face of opposition, but everyone knows that in these liberal-minded days no particular courage is required for the exhibition of such constancy. The faithful, or it may be obstinate, persons are sure of approval. Now the man who changes his mind, because to remain of the original opinion would be false to his inner convictions, has to incur the reproaches of those whose side he has left, and these are sometimes hard to bear.

THE ETIOLOGY OF CANCER.

IT is a widespread and popular idea that a blow or injury of some kind or other is sometimes followed by a malignant growth at the place in question. This view recently found expression at an inquest held by the Fulham coroner on a man, 58 years of age, a coalman, who had died in the Poor-law infirmary. It was stated in evidence that about a year ago the deceased occupied a house in Little Clarendon-street, Somers Town, and on asking one of his lodgers for rent which was owing he was struck and kicked, and that in consequence of this violence he developed cancer of the jaw and his teeth fell out. The alleged assailant and his wife, however, gave evidence at the inquest, admitting an altercation but denying the infliction of serious injury. They also stated that the incident occurred at least 23 months ago and that the deceased had previously suffered from "gumboil" and decayed teeth. Dr. C. T. Parsons, medical superintendent of the Fulham Infirmary, said that death was due to cancer of the jaw, but that it was impossible to say whether this arose from injury or from natural causes, and the jury returned a verdict in accordance with this evidence. The nature of the new growth does not seem to have been precisely described, and perhaps rightly so, for a coroner's inquest is not the proper occasion for discussing questions of histological minutiæ. Among the facts to be accounted for by those who incline to the popular view that cancer may follow an injury, are the following: that although males suffer much oftener than females from accidents and injuries yet females are much more liable to malignant disease than males; while the parts of the body most apt to be attacked by malignant growths are not the most exposed parts. Even in the female breast, one of the principal localities of selection, the disease seldom affects the nipple or the skin but usually originates as a nodule in the gland. On the other hand, there is good reason to suppose that a continuance of slight irritation may create a predisposition to cutaneous cancer, as was pointed out long ago in the case of chimney-sweeps and more recently in the case of workers in paraffin factories; while the connexion between *betel* chewing and oral cancer, to which we refer in another place, has the same probable explanation. From the frequency of malignant disease in the mouth and perioral region dental surgeons often see it in the early stage, a circumstance which provides opportunities for the exercise of skill in diagnosis and for the practical advancement of our knowledge of the disease. The "gumboil" from which the man who formed the subject of the inquest was said to have suffered may have been epulis, a chronic manifestation of alveolar sarcoma very different in its nature from an ordinary acute abscess connected with a carious tooth.

"MILK-BLENDED" BUTTER.

THERE can be no doubt that the Board of Agriculture intends to give the question of "milk-blended" butter very serious consideration with a view to check the unfair competition which its sale has introduced. A strong deputation representing the colonies as well as the mother country waited upon Mr. Hanbury at the House of Commons on May 27th and urged upon him to clear the law from the confused state in which it was at present in order that the sale of watered butter could be placed under more effectual control. Mr. Hanbury gave a very reassuring answer. He not only agreed that legislation was required but that it was required without delay. He expressed the desire of the Board of Agriculture to keep up the standard of agricultural products and to protect the public by making certain that the buyer of butter should be quite sure of getting what he asked for.

THE NAVAL MEDICAL SERVICE IN GERMANY.

IN a recent leading article[1] we called attention to the regulations which prevail in Germany for maintaining a high standard of professional knowledge in the naval medical service. Our remarks having excited some comment we think that a more detailed account of the regulations to which we alluded may be interesting to our readers. In the German naval medical service every medical officer without exception has to attend a course of four weeks' duration at the universities of Kiel, Rosto, Greifswald, and Berlin respectively. The course includes every branch of practical medicine and is given during the university holidays by the professors of the universities. The medical officers of the navy (and those of the army likewise) are ordered to attend these courses at least twice, once when in the rank of Ober-Assistenzarzt and another time when in the rank of Stabsarzt. A great many of the medical officers, though not all, have to attend the course a third time when in the rank of Ober-Stabsarzt. The courses are held at the expense of the Government. The medical officers receive their regular pay and also their travelling expenses. Medical officers of the navy who have received specially good training are allowed, or rather deputed, to hold civil appointments for one year or two years whilst continuing to belong to the service. They receive the pay of their rank during that time and at the expiration of their appointments they return to the navy. The following civil appointments are among those open to naval medical officers: assistantships at the Hamburg General Hospital, at the clinics of the Kiel University, and at the Berlin Institution for Infectious Diseases, while there are also posts at the Imperial Health Office which they may be invited to fill. Until two years ago assistantships at the Charité Hospital of Berlin were open to naval medical officers but since the complete separation of the naval medical service from the army medical service these appointments are now given to members of the army medical service exclusively. At the great naval hospitals of Kiel, Wilhelmshafen, and Cuxhafen ample opportunity is afforded to naval surgeons for professional study. From all of this it will be seen that the officers of the German naval medical service are encouraged to look upon their profession in the proper way. They are enabled at no expense to themselves, and at different points in their career, to get into touch with modern university teaching, while their professional attainments and records are taken into account in allotting to them civil appointments. The opportunities which they have of holding clinical posts in great general hospitals should be simply invaluable in keeping them up-to-date in practical therapeutics.

THE DISTRIBUTION OF PLAGUE.

THE report of the medical officer of health on the state of plague in Cape Colony during the week ending May 3rd says that at the end of the previous week six persons remained under treatment—namely, five Europeans and one native. There have been no fresh cases during the week ending May 3rd. Mr. D. C. Rees, the senior Government plague medical officer of Cape Colony, has, we understand, been appointed medical inspector on the staff of the medical officer of health of Cape Colony. A *Times* telegram dated Paris, May 27th, states that a note published by the Colonial Office announces the existence of eight cases of plague at Mojanga. There have been four deaths since May 19th. Mojanga has been declared infected and all the neighbouring ports have been informed of the outbreak of the disease in Madagascar. 33 cases of bubonic plague were reported at Hong-Kong for the week ending May 24th.

REPORT ON DIETING OF PAUPER LUNATICS IN SCOTLAND.

THE Commissioners in Lunacy for Scotland have presented a supplement to their forty-third annual report which deals with the dieting of pauper lunatics in the asylums and poor-houses of Scotland and which has been drawn up by Dr. J. C. Dunlop of Edinburgh in compliance with instructions issued by the General Board of Commissioners in Lunacy in March, 1900. A very full and exhaustive examination was made of the returns of the regulation dietaries in the various asylums and poor-houses and in many instances by visits to the institutions the returns were verified as correct. A careful study of the composition of the foodstuffs used in asylum dietaries, according to the proportions of proteid, fat, and carbohydrate present in them and estimates of their "energy values" according to established physiological principles were made. For dietary purposes the male working lunatic was considered as an able-bodied man doing a moderate day's work, as it appeared from the scheduled returns that in most asylums the working male patient was employed about six or seven hours a day at agricultural or other manual labour. The standard of energy value necessary for such a patient was taken at 3500 calories, while for the working female patient the amount estimated as required was 2800 calories, or four-fifths of that of a male. It was also calculated that the average male asylum dietary should have an energy value of 3000 calories per male patient and 2650 calories per female patient when both working and idle patients were considered. On the basis of these requirements the various dietaries were critically examined. Attention was also paid to the facts that variety in food and a proper supply of fresh vegetables and of condiments were a *sine qua non* for all dietaries, as it was only when these conditions were satisfied that any dietary could be regarded as adequate. Calculations were then made of all the dietaries as regards their food value and the results were classified into three groups—viz., dietaries which were excessive, dietaries approximating to the standard, and dietaries which were defective. Thus among the dietaries for male patients in 39 specified institutions 11 were found to be excessive, 13 were approximately standard, and 15 were deficient; and among the corresponding dietaries for female patients 25 were excessive, eight were approximately standard, and six were deficient. Excessive feeding was thus found to be more prevalent in female than in male departments, and it was clearly evident, says the report, that some of the dietaries might safely be reduced and others with much advantage might be increased. Excess of carbohydrate food was noted in the dietaries of three institutions. The report concludes with valuable suggestions regarding the proper feeding of asylum patients. Bread is recommended to be given *ad libitum* with all meals, "an improvement which is called for in nearly all the asylum dietaries," and little fear is entertained of undue waste arising from this source. The minimum weekly amount of meat uncooked without bone should be 24 ounces per patient distributed into four meals, of potatoes three pounds, and of other fresh vegetables one and half pounds. A fish dinner, or a fifth meat dinner, should be given weekly. The weekly allowance of butter should be not less than five ounces and tea, coffee, or cocoa should be given twice in each week. The report forms an important document on the dietetics of the insane in pauper asylums.

---

[1] THE LANCET, April 26th, 1902, p. 1193.

THE DUST PROBLEM ON THE RIVIERA.

THE motor car has produced one great evil—it has caused a most serious increase in the quantity of dust on the roads. On the Riviera, where the motor-cars are numerous, the nuisance is so great that it has been described as "the dust plague." Even the strong and healthy feel the discomfort, and invalids, especially those with affections of the chest for whom the Riviera has been a favourite resort, are beginning to find the place intolerable. With considerable ingenuity and assiduity Dr. Guglielminetti of Monte Carlo has endeavoured to find a remedy for the evil. In the *Gazette Médicale de Paris* of May 17th he advocates as the result of his labours the tarring of the roads. Thorough watering would be very expensive. The use of sea water is open to the objection that after evaporation salt would remain which would injuriously affect the eyes of pedestrians and the dresses of ladies. Moreover, the heat is so great that the roads rapidly dry after being watered. Dr. Guglielminetti therefore turned his attention to the processes which have been substituted for watering roads. In California and other American districts water has given place to petroleum as a dust-layer. In Algiers olive oil and naphtha oil have been used since 1896. The American method is to cover the roads with a layer of heavy unrefined petroleum heated to 80° C. An asphalte-like deposit, which is solid and durable and forms but little dust in summer and no mud in winter, is formed. This roadway is greatly appreciated by cyclists and drivers and a saving of 45 per cent. of watering expenses is effected. Two applications of petroleum a year are sufficient; 5000 litres of petroleum, which cost 400 francs, are required per kilometre. But in France the cost would be five times as much. Dr. Guglielminetti therefore turned his attention to coal-tar which has been applied to roads in the Haute Garonne and in Ravenna in 1901. In the latter town 246 metres of roadway were treated with excellent results. The authorities at Monte Carlo have been induced to try the tar method on [illegible] the Vaccinão, the slaughter-house. In [illegible] obtained exemption certificates for the results surpassed hard and compact that it was difficult to break up. There was no dust and rain did not penetrate the layer formed by the tar. After 40 days' traffic the surface was not damaged and had resisted the wear and tear of wheeled traffic. The cost was from six to seven centimes per square metre. The prefect of Alpes Maritimes and the engineer-in-chief of roads and bridges have favourably received the idea and are willing to allow experiments on public roads provided that they are made at private expense. The municipal authorities and hotel-keepers of Monte Carlo are moving in the matter. We trust that Dr. Guglielminetti's efforts to combat "the dust plague" will be crowned with the success which they deserve.

VOLUNTARY AID FOR THE SICK AND WOUNDED IN SOUTH AFRICA.

AN account of the voluntary organisations in aid of the sick and wounded during the war in South Africa has just been issued in the form of an interesting and instructive Blue-book,[1] illustrated by a number of well-executed reproductions of photographs and diagrams. In the book will be found articles dealing with the work of the National Aid Society, the Red Cross Commissioners in South Africa, the St. John Ambulance Association and St. John Brigade, and the Army Nursing Service Reserve, together with a description of the hospital ships and trains. The work of the foreign Red Cross societies is described and there is an account of the voluntary aid received from British colonies and other British possessions. Private hospitals and minor schemes also receive notice and there is a chapter on the organisation of convalescent homes in the United Kingdom. The object of the report is not so much to give an account of the actual work done as to indicate the manner in which the several schemes were initiated and carried out; and as showing generally the resources that are likely to be made available in future wars the information contained in the pages of the report is of great value. It is interesting to note that "the total value of the voluntary aid resources placed at the disposal of the sick and wounded of the army must have amounted to close on £1,000,000." Among the conclusions arrived at in the final chapter of the report are that the voluntary aid organisations such as exist in connexion with continental armies are not applicable to the genius and spirit of the British nation and that the best organisation for this country would be the formation of local committees in time of peace.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

ON the occasion of the annual dinner of the members of the Pharmaceutical Society of Great Britain at the Whitehall Rooms, Hôtel Métropole, on May 27th, presided over by Mr G. T. W. Newsholme, the speeches turned chiefly upon the desirability of pharmacy having a representative in the House of Commons. There are certainly points connected with the administration of the Pharmacy Act and the sale of poisons which can only be properly understood by a pharmacist. Sir William Church, in reply to the toast of "The Medical Profession," agreed that it was desirable that his own profession should have a better knowledge of pharmacy and should pay greater attention to pharmacology than they had done before. He instances the extraordinary ignorance shown by some candidates at medical examinations of the composition of simple and familiar preparations of the British Pharmacopœia. It was only quite recently, he said, that it had been discovered that ferrum redactum invariably contained arsenic, which obviously must seriously modify the therapeutic action of the preparation. Referring to the bibliography of the subject he thought that the first pharmacopœia was issued at Nuremberg, although some held that drugs and their preparations were codified for the first time at Florence. Mr. H. G. Howse acknowledged that the medical profession was greatly indebted to pharmacists for the extraordinary advances which they had made in regard to the purity and preparations of drugs and to their standardisation and accuracy of dosage. The dinner was very well attended and amongst those at the President's table were Sir Frederick Abel, Dr. J. Attfield, F.R.S., Sir J. Crichton Browne, Professor Norman Collie, Sir William Church, President of the Royal College of Physicians of London, Sir Dyce Duckworth, Mr. H. G. Howse, President of the Royal College of Surgeons of England, Dr. W. H. Allchin, Dr. Donald McAlister, Sir William Turner (President of the General Medical Council), and Professor W. A. Tilden, F.R.S.

---

[1] Report by the Central British Red Cross Committee on Voluntary Organisations in Aid of the Sick and Wounded during the South African War. London: His Majesty's Stationery Office.

DYED MILK.

EVIDENCE is accruing that the practice of adding artificial colouring matter to milk is increasing. Samples are commonly met with thus coloured to give them a rich but false creamy aspect. The natural colour of milk bears no relation necessarily to the amount of cream present. It is very desirable that this practice should be stopped. The recommendation of the Departmental Committee on Preservatives and Colouring Matter in Food that the use of any preservative or colouring matter whatever in milk offered for sale in the United Kingdom should be constituted an offence under the Sale of Food and Drugs Act should speedily be put into force. We believe that annatto is the dye commonly employed and it is fortunate that it is harmless, though that fact does not justify the device. Certain coal-tar dyes have, however, been detected in milk and amongst them methyl-orange or, in chemical nomenclature, the sodium salt of dimethylaniline azobenzene-sulphonic acid.

POISONING FROM THE APPLICATION OF CARBOLIC ACID TO THE UNBROKEN SKIN.

WE have published some cases of poisoning by carbolic acid from application of compresses to the unbroken skin.[1] In the following case, which is recorded in the *Boston Medical and Surgical Journal* of April 3rd by Dr. J. W. Wainwright, the same result was produced by the simple application of carbolic lotion to the skin. A vigorous man, aged 50 years, used a 2 per cent. solution of carbolic acid as an application for pruritus with temporary relief and without ill-results. One day at noon, after taking a hot bath, he used a 4 per cent. solution. He applied it to the abdomen, the thighs, and the lumbar region with the usual relief. At 7.30 next morning while dressing he suddenly felt a peculiar pain which he referred to the bladder. It increased and radiated through the abdomen. He could not finish his toilet and the administration of morphine became necessary. A quarter of a grain was injected without relief and the dose was repeated in half an hour. There were frequent rigors, each of which lasted for a few minutes, profuse cold perspiration, vomiting, and a desire to defecate. The eyes were prominent and fixed. There were vertigo and weakness of the lower limbs. After one and a half hours another quarter of a grain of morphine was injected. For 18 hours no urine was secreted. Appendicitis, renal calculus, and ptomaine poisoning suggested themselves. Four and a half hours after the onset of symptoms he became drowsy and would doze for a few minutes to be awakened by the recurring pains. The pulse was frequent and at times barely perceptible and the skin was moist and cold. Relief from pain began about four hours after the onset of the symptoms and at midnight he was comparatively comfortable. Examination of the urine revealed the characteristic smoky appearance of carboluria. For three days there were great depression and symptoms of acute nephritis. Recovery was complete in 10 days.

THE PREVALENCE OF SMALL-POX.

ON Saturday, May 24th, 50 cases of small-pox were admitted to the institutions of the Metropolitan Asylums Board; on Sunday, May 25th, 43 cases were admitted; on Monday, May 26th, 58 cases were received; on Tuesday, May 27th, 32 cases were accepted; and on Wednesday, May 28th, 35 cases passed through the hands of the authorities. In the county of Essex the small-pox cases notified for the week ending May 24th numbered 50.

AN ANALYSIS OF 155 CASES OF TABES DORSALIS, WITH ESPECIAL REFERENCE TO CAUSATION, SYMPTOMS, AND LENGTH OF LIFE.

IN the Spring Number of *Brain*, 1902, Dr. Byrom Bramwell publishes a lengthy and interesting article based on an analysis of 155 cases of tabes dorsalis met with in hospital and private practice. In a considerable proportion of the cases the course of the disease was followed during periods of several years and in most of the fatal cases the total duration of the disease and the immediate cause of death were ascertained. Of the total number of cases 140, or 90·3 per cent., were males, and 15, or 9·6 per cent., were females, a proportion which agrees closely with that of Gowers—viz., 10 males to one female. The ages at which the first symptoms of disease developed were noted in 151 cases, and in 112 of these, or 74·1 per cent., the disease commenced between the ages of 30 and 50 years. As regards etiology, syphilis was ascertained to have existed in 59·8 per cent., in the remaining cases its existence was doubtful or denied or not ascertained. The percentage of cases in which a definite history of syphilis was obtained was, however, higher in the last than in the first moiety of cases, probably because, as Dr. Bramwell thinks, the inquiries made were more stringent. In three at least of the syphilitic cases the patient had been treated very thoroughly for long periods of time with mercury and yet developed tabes, showing, says Dr. Bramwell, that prolonged and thorough mercurial treatment did not, in all cases, prevent the subsequent appearance of tabes—an important practical point as regards life insurance. The length of time between syphilitic infection and the development of tabes was less than 20 years in the vast majority (91 per cent.) of cases, the second, third, and fourth quinquennium after infection claiming each nearly a fourth of the victims. As regards general physique it was noted that many of the patients were robust and strong men of fine muscular development. Dr. Bramwell regards syphilis as the most important, but not the sole, cause of tabes dorsalis. The toxins produced by the syphilitic virus, says Dr. Bramwell, have a widespread effect upon the nervous system, rendering it liable to be affected injuriously by other conditions such as various forms of strain and irritation (including exposure and alcoholic or sexual excesses) which are probably the exciting causes. The commonest initial symptoms were "lightning pains" in 53 per cent. of the cases, diplopia and ataxia in 8·6 per cent. each, loss of vision in 6 per cent., derangements of urination in 4 per cent., gastric crises in 3·3 per cent., and numbness in the feet in 2 per cent. Lightning pains were also the commonest symptoms in the course of the disease. They were present in 148 out of the 155 cases, or 95·4 per cent., and were in every case felt in the legs and less often in the trunk, arms, and head. In several cases in which optic atrophy developed the severity of the lightning pains lessened with the loss of sight. The relative frequency of the other symptoms was as follows: loss of knee-jerk was present in 82 per cent. of the cases, ataxic gait or ataxia in standing with the eyes closed in 77 5 per cent., derangements of the bladder in 74 per cent, and Argyll-Robertson pupil in 72 per cent. Mental symptoms in the form of general paralysis developed in 16 cases, impairment of memory was noted in five cases, and mental depression in four cases. In the great majority of cases, however, mental activity was unimpaired, even in the later stages of the disease. As regards prognosis it appeared that 31 of the 155 patients were dead, 75 were alive, and 49 could not be traced at the time of writing the article. Of the 31 fatal cases the average duration of the illness was 8 3 years, the longest being 22 years and the shortest one and a half years.

---

[1] THE LANCET, April 6th, 1901, p. 1011.

THE MEDICAL SOCIETY OF LONDON.

THE annual conversazione of the Medical Society of London was held on May 26th. After a reception by the President, Dr. W. H. Allchin, the annual oration was delivered by Dr. Stephen Mackenzie on the Powers of Natural Resistance or the Personal Factor in Disease of Microbic Origin. This excellent address is published in full at page 1513 of our present issue. A vote of thanks to the orator was proposed by Dr. Sidney Coupland and seconded by Mr. J. Bland-Sutton. Music was provided in the hall and in an adjoining room there was exhibited a collection of etchings and drawings of Old London and its vicinity belonging to Mr. Jonathan Hutchinson, jun., who was himself in several instances the artist. The collection included certain of Whistler's "Set of Thames Etchings," among others the famous "Limeburner" and "Rotherhithe" (the largest plate in the set), a fine impression of Sir F. Seymour Haden's magnificent etching, "The Breaking up of the *Agamemnon*," "The Guardship at the Nore" by J. M. W. Turner (a beautiful rendering of sea-scape), and Mr. D. Y. Cameron's "London Set." Among the miscellaneous etchings and drawings from Mr. Hutchinson's pen we may choose for particular commendation "Southwark Bridge from St. Paul's Wharf Pier." The collection was a remarkable one and its contemplation formed an agreeable change to the ordinary routine of these functions.

SUPPURATIVE PERIODONTITIS—PYORRHŒA ALVEOLARIS.

IN the last issue of the Transactions of the Odontological Society of Great Britain Mr. Kenneth Goadby publishes a preliminary account of his investigations into the pathology of suppurative periodontitis. One point of some interest would seem to be that cultural examinations have demonstrated in many cases the presence of members of the yeast family in the discharge from the sockets of the teeth. Mr. Goadby has, moreover, found yeast in the small masses of tissue adhering to the apices of teeth extracted in cases of suppurative periodontitis, and culturally he finds they appear to correspond to the yeasts found in the so-called chronic abscesses. From direct examinations of the pus he finds a marked difference in the species of bacteria morphologically represented in early and late cases, it being rare to find many cocci present in the later stages, the field being, as a rule, occupied by bacilli of various kinds and a good number of threads, the latter showing a tendency to stain irregularly and in patches. In discussing the question of the causal relation of certain bacteria to suppurative periodontitis he refers to an organism, a coccus hitherto not described. This organism is frequently present in cases of dento-alveolar abscess and appears to have some relation to the curious thick viscid pus found in some cases of suppurative periodontitis. The coccus is also found in septic pulpless teeth associated with abscesses. It produces a marked stringy viscous growth upon solid media and is extremely difficult to remove from the agar slant. The broth cultures also form stringy viscous growths, which at times adhere to the sides of the tube in the form of a cloud of colonies about 0·5 millimetre in diameter that are strongly adherent to the glass. Mr. Goadby considers it highly improbable that the ordinary pus organisms have any direct share in the production of suppurative periodontitis.

CANCER IN INDIA.

THE subject of cancer in India is exciting some interest at the present time in connexion with the scheme which has been launched in this country for the organised investigation of that and other allied forms of malignant disease. The *Indian Medical Gazette* for the month of May contains two excellent papers having a direct and special bearing on the subject. The first is by Captain W. J. Niblock, I.M.S., of the General Hospital, Madras, embodying the results of the experience obtained at that hospital, for which purpose the hospital registers for the past 10 years have been carefully gone through. All cases of carcinoma, sarcoma, and rodent ulcer—using the term malignant disease as synonymous with that of cancer in its broader sense—which have been admitted into that institution have been extracted, tabulated, and analysed. The other paper, by Dr. Ernest F. Neve, briefly summarises the history and results of "A Decade of Tumour-Surgery in the Kashmir Mission Hospital." While there are no published statistics showing the frequency of admissions for cancer in the various hospitals throughout India, together with the regions of the body affected, cancer seems to be in Madras, at any rate, by no means rarely met with, and the same may be said of Kashmir. In looking over the tables compiled from the Madras Hospital registers one of the first things to strike us is the enormous number of native patients admitted for carcinoma of the cheek and jaws—a fact which is stated, and apparently on strong grounds, to be accounted for by the habit prevalent among Hindus and Mahomedans of both sexes of the chewing of *betel*. In Dr. Neve's paper it is stated that the total number of tumours operated upon between the years 1890 and 1899 was 2020, more than 50 per cent. of these being malignant.

ASSOCIATION OF ASYLUM WORKERS.

THE annual meeting of this association, formed in 1895 to promote the interests of asylum workers by improving their status and enlisting public sympathy in their work, was held on May 22nd at 11, Chandos-street, London, W., Sir James Crichton Browne presiding. There was a large attendance of medical officers of asylums and the Commissioners in Lunacy were represented by Dr. Sidney Coupland. A considerable number of nurses and attendants were also present. After the election of the officers and executive committee the President (Sir J. Crichton Browne) moved the adoption of the report (which was presented by the honorary secretary, Dr. G. E. Shuttleworth) in an interesting speech in which he reviewed the work of the association. The membership had increased from 2868 in 1900 to 4116 in 1901, and several additional asylums in all parts of the kingdom were now represented on the roll. The monthly organ of the association, *Asylum News*, had been from time to time enlarged, and its present size demanded, for free distribution among members, an increase of the annual subscription from 1*s.* to 1*s.* 6*d.*, which had been cheerfully conceded. In addition to intelligence of special interest to asylum workers the journal had contained valuable articles upon nursing the insane and upon other matters of an educational character. Sir J. Crichton Browne advocated the culture of the literary faculty amongst asylum workers, specially recommending the reading of sound novels, "free from insanity and idiocy," as a wholesome recreative measure. Referring to lunacy legislation he thought that there was no immediate prospect of its introduction, but he hoped that when a Bill was forthcoming they would obtain a modest provision for old age or for any disability incurred in the course of duty. One of these days the increase of insanity and of all nervous diseases would startle the public, and then perhaps justice would be done to those battling with this stupendous social evil. The adoption of the report (with a code of rules) was seconded by Dr. T. B. Hyslop and was carried. The distribution of two gold medals and two silver medals for long and meritorious nursing service in asylums followed, the former being awarded respectively to Mr. W. Hope, now inspector at Colney Hatch Asylum (36½ years' service), and Miss M. Riches, head nurse at Heigham Hall Asylum, Norwich (35½ years' service); and the latter to Miss A. Garry, chief nurse at Gloucester County Asylum (28½ years' service), and Mr. C. Walker, charge attendant at Caterham Asylum (28½ years' service). By the kind liberality of the President bronze medals were also given to 28 approved competitors for the association medals in recognition of their high recommendations. A vote of thanks to Sir James Crichton Browne, moved by Dr. Oscar T. Woods, President of the Medico-Psychological Association, brought the proceedings to a close.

MEDICAL REPORTS OF THE CHINESE IMPERIAL MARITIME CUSTOMS.

THE medical reports of the Chinese Imperial Maritime Customs deal with the health conditions of the European population in several Chinese cities and are written by the Customs medical officers there stationed.[1] The contributors to the present series, together with the names of their respective towns, are as follows:—Dr. William Kirk, Ichang; Dr. J. D Thomson, Hankow; Dr. H. J. Hickin, Ningpo; Dr. R. J. J. Macdonald, Wuchow; Mr. J. H. Lowry and Dr. H. M. McCandliss, Hoihow and Kiungchow; Mr. A. S. Deane, Pakhoi; and Dr. Ortholan, Szemao (who writes in French) The periods under consideration are either the year or the half-year ended Sept. 30th, 1900. Dr. Thomson discusses a variety of medical and surgical questions at some length and gives detailed clinical histories of cases of malaria, enteric fever, heat-stroke, and dysentery. In the treatment of malaria he used quinine both by the mouth and hypodermically, as well as calomel purges, frequent sponging, guaiacol inunctions, phenacetin, antikamnia or antifebrin combined with caffeine, digitalis, and brandy. One of the malaria patients was suffering from his third attack of the pernicious algid type and his symptoms closely resembled those of the collapse stage of cholera. Another had many injections of quinine between the shoulders without any untoward result, but an injection of 15 grains of the sulphate dissolved with the aid of hydrochloric acid and divided between the two thighs caused much inconvenience. In one thigh the solution was injected under the deep fascia and three days afterwards there was high fever with painful swelling and emphysema of the tissues. These alarming symptoms, however, subsided rapidly without leaving any ill-effects behind them and Dr. Thomson thereupon ascribed the evolution of gas to the contact of the acid of the injection with the alkaline juices of the tissues. In the other thigh, where the remainder of the dose was injected into the subcutaneous tissues, these broke down for a considerable distance and a portion of skin measuring about one inch by half an inch became necrosed. The patients suffering from heat stroke, three in number, all had axillary temperatures of 110° F. and all died. Among the illustrations Dr. Thomson gives a reproduction of a skiagram of the Chinese woman's "small foot." Dr. Macdonald states that in Wuchow the plague was even more severe in 1900 than in the previous year Dr. McCandliss and Mr. Deane also make reference to the presence of plague in their towns, not, however, among the European community.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

IN 1901, as in previous years, the Royal London Ophthalmic Hospital accomplished much beneficent work but a perusal of the annual report makes it only too obvious that the usefulness of the charity is sadly impaired by want of funds. The total number of in-patients during the year was 1866. Out of an aggregate number of 138 beds 68 were compelled to be unoccupied by reason of financial straits, so that there remained only 70 beds available for in-patients, and of these the average number occupied was 64. The new out-patients numbered 31,258 and the total number of attendances was 100,673. The year 1901 began with a financial deficiency of £2591 and the excess of expenditure over income during the ensuing 12 months amounted to £2577, making a total deficiency at the end of last December of £5169. It was, in fact, only by raising a loan of £5000 from the Charity Commissioners that the committee was able to keep the hospital open during the year. The grants from the three hospital funds for London amounted to £2067—namely, £623 10s from the Hospital Sunday Fund, £193 10s. from the Hospital Saturday Fund, and £1250 from King Edward's Hospital Fund; the latter fund also contributed an additional sum of £900 as an annual grant to open 18 closed beds, on the condition that by the opening of these beds 18 more were made available for the sick poor. One of the most pressing difficulties of the hospital since its removal from its old site to the better one which it now occupies has been the question of local rates and the item of £948 charged under this heading in the expenditure seems to be disproportionately high, exceeding as it does the combined outlay for meat and grocery. The exemption of hospitals from local rates is a subject which has on various occasions been discussed in our columns, and the present case is undoubtedly one in which some such relief is urgently needed. In addition to a special appeal for further annual subscriptions the committee asks for donations to the Rent Fund, the interest of which is to be devoted towards meeting the ground rent of £1210 per annum.

THE Duke of Connaught has fixed Friday, June 20th, at 4 P.M., for the laying of the foundation-stone of the new buildings of Charing-Cross Hospital. His Royal Highness, as M.W Grand Master of the United Grand Lodge of England, will perform the ceremony with full Masonic honours and will be attended by the officers of Grand Lodge.

MR. ALBAN H. G. DORAN has been appointed to deliver the Harveian Lectures for the Harveian Society next November and has chosen for his subject "Uterine Fibroids considered from a Clinical and Surgical Standpoint"

THE Princess Christian of Schleswig-Holstein will open the new home for the nurses in connexion with Friedenheim Hospital (Home of Peace for the Dying) on Saturday, June 7th.

AT Merthyr Tydvil police-court on May 12th the magistrates selected Mr Cornelius Biddle, L.R.C.P. Lond., M.R.C.S. Eng., to be high constable of the town for the ensuing year.

OBSERVATIONS ON DIET.

BY HARRY CAMPBELL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL; PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES, WELBECK STREET, W.

II.—QUANTITY OF FOOD (*continued*).[1]

Excessive Dietary.

Inducements to over-eating.—Animals in a state of nature are little likely to over-eat—first, because their constant search after food entails a highly active life and this demands a correspondingly large supply of food; secondly, because their food, except in the case of the carnivora, is seldom in a highly concentrated form; and, finally, because it is of such a simple and monotonous kind that the appetite is appeased when a sufficiency has been consumed; so that, far from having a surfeit, most animals have as much as they can do to obtain the needful supply. Civilised man, on the other hand, is not only not compelled to lead a muscularly active life, often taking little or no exercise at all, but his food is highly concentrated, consisting largely of such articles as sugar, butter, cheese, and meat, and far from being monotonous it is of a varying kind, and in the case of the well-to-do is rendered appetising by the manifold resources of the culinary art. While, then, it is practically impossible for a wild animal habitually to over-eat the modern Human has many inducements to tempt him to excess and as a matter of fact he often yields to them. In this respect men are greater sinners than women.

Extreme instances of over feeding.—Some remarkable instances of gourmandising have been placed on record, but how far they are legendary and how far genuine it is difficult to say. They are told chiefly of the inhabitants of cold climates. The Esquimaux, it is said, eat as much as 20 pounds of flesh and oil daily. We have it on the authority of Sir George Simpson that two Yakuti men ate at a sitting 36 pounds of beef and 18 pounds of butter each. He remarked that "after such surfeits the gluttons remain for three or four days in a state of stupor, neither eating nor drinking, and meanwhile are rolled about with a view to promoting digestion."

EVILS OF OVER-EATING.

Over-distension of the stomach.—One of the immediate effects of a surfeit is undue distension of the stomach which may not only cause organic dilatation of this organ but, by thrusting the diaphragm upwards, compress the lungs and dislocate the heart, disturbing its action even to the point in extreme cases of checking it altogether. Those with failing hearts or feeble breathing power should beware never to overload the stomach; their maxim should be "little and often." Meals that are few and far between are apt to be unduly bulky. When, for instance, only one meal is taken in the day the individual, especially if leading an active life, is compelled to consume at one sitting more food than the normal stomach can hold and dilatation is the necessary consequence. Moreover, this large mass of food makes such demands upon the digestive organs as to render the individual for the time being lethargic and inert. The one-meal plan also leads to wastage, for when a large quantity of food is taken at once and the blood is surcharged with nutriment much of it is, as already hinted, apt to be katabolised as so much useless excess in the hours immediately following the meal. It is a fact, however, that many races subsist on a single daily meal. This is the case with the majority of the natives of India and doubtless the system is suited to their requirements, though one would have thought that the bulkiness of their diet, which is mainly vegetarian, would constitute a serious objection to the custom.[2] But whatever may be true of certain of the inhabitants of warm climes the fact remains that the plan of taking but one meal a day is not suited to the average European. For him three meals during the 24 hours would appear to be on the whole the wisest arrangement.

A further word on the subject of over-distending the stomach. It has to be noted that a diet may cause undue distension of the stomach without being excessive—namely, by containing a large quantity of non-nutrient substances, as in the case of green vegetables, or by causing flatulence. Accordingly, when it is desirable to distend the stomach as little as possible we prescribe concentrated foods and such as are least likely to cause flatulence, and we forbid the drinking of large quantities of fluids with meals. It is now known that very little fluid is absorbed by the stomach, and consequently when liquid is taken at meal-time it has to wait for the food to be digested before it can escape into the duodenum, thus adding materially to the bulk of the gastric contents. Fluid taken with meals may also retard digestion by diluting the gastric juice, though it is doubtful whether much harm is done in this way. It is, moreover, often used as a means of softening the food and washing it down, and may thus do harm by encouraging the individual to shirk mastication. For these reasons liquids should for the most part be taken on an empty stomach, say half or three-quarters of an hour before meals, so as to give time for them to leave the stomach before food is eaten. Hence, too, the advantage of giving aperient salines on an empty stomach—e.g., the first thing in the morning.

Excessive storage of fat.—The most obvious evil result of chronic over-eating is obesity. In some cases obesity is a disease—e.g., in myxœdema and in certain obscure diseases of the nervous system in which there may be a phenomenal laying on of fat. I have seen two such cases in children. In the majority of instances, however, it is due to over-eating. We have seen that the amount of food required is governed by several circumstances, of which the most important is the amount of exercise taken, and as might be expected the obese person generally takes very little. Those who exercise their muscle system a great deal are but rarely obese; I do not remember ever to have seen a fat postman and a fat navvy is rarely met with. Let the fact then honestly be faced by the obese that except in those rare cases which are due to disease inordinate fatness is due to over-eating and should be met by apportioning the diet to the needs of the individual.

Evils in connexion with the Blood and Circulation.

The digestion of food imposes extra work on the heart by the increased activity of the splanchnic circulation which it entails, and when a large quantity of food is taken there is a substantial augmentation of cardiac action.[3] If, therefore, we are dealing with a case of grave cardiac failure where it is of paramount importance to save the heart as much as possible we see how imperative it is that we should administer food sparingly. An excess may, moreover, as we have seen, disturb the action of the heart both by distending the stomach and by inducing obesity. It may also affect it, as we shall see in due course, by increasing peripheral resistance and through its influence on respiration.

Plethora.—Just as starvation tends to impoverish the blood and to diminish its mass, so may over-feeding cause excessive richness of the blood, and perhaps also augmentation of its mass. Cohnheim denied the possibility of the latter, but, be this as it may, it is certain that the condition known as plethora, characterised by vascular turgescence of the face and often accompanied by a feeling of fulness in the head, giddiness, and other symptoms, all of which are relieved by bleeding, may result from chronic over-eating. Whether there is an actual augmentation of the blood-mass in these cases, or whether, as some think, the condition is rather one of arterial plethora due to high peripheral resistance with a powerfully acting heart, is a question which we need not stop to discuss.

Anæmia.—Curiously enough, over-eating may lead to the opposite condition, anæmia, not indeed to a diminution of the blood-mass (oligæmia), but certainly to a defective condition of the chromocytes. It is now known that these are very susceptible to the action of toxins which, as we shall see, are apt to abound in the chronic over-eater, and possibly the blood corpuscles suffer from their action. Certain it is that some patients improve in colour when their diet is cut down.

Evils in connexion with the Respiratory Function.

The influence of over-eating on respiration is not less important than is its influence on the circulation. The obesity which it so frequently causes seriously interferes with the respiratory movements. A distended stomach, moreover, thrusts the diaphragm upwards and thus restricts the of a hospital exclusively American in its management. This is about to be realised through the generosity of Mr. Edward Tuck, formerly of New York but for 20 years a resident in Paris. He has assumed the entire expense of establishing this hospital which is to be managed entirely by American physicians and nurses. It is to be called the "Franklin Hospital" and will be located in the Passy quarter, one of the most healthy parts of the city. The site has been purchased and the erection will begin in the spring under the directorship of Dr. Magnin.

---

[1] No. I. was published in THE LANCET of May 24th, 1902, p. 1486.

[2] One may, perhaps, explain the ability of the Oriental to subsist on one meal a day by the fact that living as he does in a warm climate he requires less food than the inhabitant of colder climes, and by the further fact of his food consisting mainly of saccharide which admits of ready storage.

[3] Cohnheim gives hypertrophy of the heart as one of the results of gourmandising.

March 24th.

Obituary.

EDWARD LONG FOX, M.D OXON., F.R.C.P. LOND,

CONSULTING PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

THE West of England has lost one of the most representative members of the medical profession by the death of Dr. Edward Long Fox of Clifton, which occurred late on Friday evening, March 28th. He was in active practice till some months ago when his health failed, and though with characteristic determination he at first looked forward to resuming again the work he so dearly loved it soon became increasingly evident that he was beyond hope of recovery. Dr. Fox was the eldest son of the late Dr. Francis Ker Fox of Brislington, near Bristol, where he was born in 1832. He was educated at Shrewsbury School and Balliol College Oxford, where he was brought under the influence of the late Professor Jowett, who was his tutor, and of Sir Henry Acland. The warm friendship and esteem of these representatives of the classical and scientific life at Oxford for their former pupil were never interrupted while they lived and the latter was one of the earliest and most welcome guests when Dr. Fox began his professional career in Bristol His special bent was shown by taking a first-class in the Natural Science School, after which he proceeded to London to the College of Chemistry under Dr. Hoffmann and entered as a student at St. George's Hospital At this and at the Great Ormond-street Hospital for Sick Children and the Brompton Hospital for Consumption Edward Long Fox worked especially under Dr. Bence Jones, Dr Marshall Hall, and Dr. Charles West, till he graduated as M B. in 1857, proceeding to the degree of M.D in 1861. In 1859 he became a Member of the Royal College of Physicians of London.

He then commenced to practice in Clifton and was elected a physician to the Bristol Royal Infirmary, a post which he held for 20 years when he was made a consulting physician, being thus connected with that institution for 45 years. He was also lecturer on medicine and on practical pathology at the Bristol Medical School and always took the keenest interest in his teaching and in the welfare of the students working under him, many of whom now engaged in active practice remember with loving regret the friend who has passed out of their lives.

For several years Dr. Fox was examiner in medicine in the final examination for the degree of M.B. at the University of Oxford. He became a Fellow of the Royal College of Physicians of London in 1870, delivered the Bradshaw Lecture in 1882, and was elected a member of the Council of the College in 1888.

When the British Medical Association held its annual meeting in Bristol in 1894 Dr Fox, already a past president of the Bath and Bristol Branch of the Association and of the Bristol Medico-Chirurgical Society, was elected President. His genial presence and warm-hearted hospitality added much to the pleasure of those who took part in that meeting, while his earnest desire that the scientific work done should be worthy of the Association and of the city of Bristol was largely attained by the cordial coöperation which both his medical colleagues and fellow citizens were so ready to afford. The lofty aspirations and high professional ideals which the life of Dr Fox so well exemplified were reflected in the presidential address at that meeting on the Medical Man and the State, when he said: "The sands of time are sinking year by year for all of us; but the memory of the great ones in the past is a spur to further effort, an example for a truer and higher life in us all; and happy shall we be if we can pass on undimmed to our successors the lamp of high professional honour and of scientific attainment which has been handed down to us from our predecessors." No one evinced a greater interest in the work of the National Association for the Prevention of Consumption than did Dr. Fox, and he it was who took the first steps in the movement which eventuated in the formation of the Gloucester, Somerset, and Wilts branch. Up to a few months ago he filled the office of chairman of the committee of this branch and many of his fellow-workers in the cause will remember his untiring interest, despite his physical weakness, in the work of inspecting the beautiful site found and suggested by Dr. Lionel A. Weatherly and so recently prepared for the proposed sanatorium at Winsley.

Dr Fox took a great and broad-minded interest in the temperance question, being president of the National Temperance League in 1894, he also for several years personally worked on behalf of the temperance cause in one of the poorest parishes of Bristol. Dr. Fox was the author of works on "The Pathological Anatomy of the Nervous Centres" and "The Influence of the Sympathetic on Disease," which were published in 1885. He also contributed various articles to the medical journals and a series of articles to "Quain's Dictionary of Medicine." He married Miss Bradley, one of the daughters of the late Rev Charles Bradley of Clapham and sister of the present Dean of Westminster The Dean of Bristol, in preaching at the Cathedral on Easter Day, referred in sympathetic terms to the death of Dr Fox, of whom he spoke as a type of the Christian physician The burial took place on April 3rd at Arno's Vale Cemetery, the first part of the burial office being said in Clifton Parish Church at 12 30.

JOHN TURNER CADDY, M.D. ABERD.

DEPUTY INSPECTOR-GENERAL OF HOSPITALS AND FLEETS, R.N

THE death took place on March 21st of Dr J T Caddy, Deputy Inspector-general of Hospitals and Fleets, R.N (retired), at his residence, The Charterhouse, Richmond, Surrey Dr Caddy was 80 years of age, of which 31 years were spent at sea and many on the training ships for men and boys at Falmouth and Bristol. He was in receipt of the Greenwich Hospital good service pension. In conjunction with the late Sir William Smart and Dr. Frederic James Brown he took a leading part in the movement for the "consideration of the rank, pay, and position of medical officers in the Royal navy" 50 years ago and his views were quoted in Parliament by Mr Wakley, M.P, the coroner for Middlesex, with excellent effect. Dr. Caddy was of an old Devonshire family and after being apprenticed to a practitioner for five years he finished his medical studies at Guy's Hospital where he succeeded in winning several prizes. He was the author of several contributions to the medical journals and of papers read before learned societies Two of his sons and his son in law are members of the medical profession.

Medical News.

VICTORIA UNIVERSITY —At the degree ceremony on March 28th the following candidates were presented:—

BACHELOR OF MEDICINE AND OF SURGERY.

Edward Maynard Ashcroft and Frank Henry Staunton Ashworth, Owens; Herbert Martin Berry, University, Arthur Torkington Blease, Joseph Basil Cook Rowe Drennand Fletcher, James Edward Floyd, James Hindshaw, and Hugh Llewellyn Jenkins, Owens; John Anderton Johnson, University; Charles Paget Lapage and Harry Fox Lee, Owens, William Leonard Maccormac, Yorkshire; Harold Scott McLellan, William Parker, and Charles Albert Hickotts Owens; E Emrys Roberts, University, and George Taylor, Owens

In the Faculty of Medicine the following candidates have been successful in the examinations indicated.—

FINAL EXAMINATION.

Part I—J W. Anderton Owens; P. W. Ashmore, Yorkshire; J. P Bligh, University, L. R Braithwaite, Richard Coates, and Edward Cundall, Yorkshire; A. J. Edmunds, A. H. Gregson, Godfrey Heathcote and *Benjamin* Herald, Owens; W. E. Hewitt, University; B. H Hirst, Yorkshire; A. S Hopper, University; A. R. Johnson, Owens; R E Knowles, W. G. Lloyd and H. P. McManus, University, Harry Mallin, Yorkshire; W. B Ramsden, Owens; F. H Salisbury University, F. E Steele, J. C. Teasdale, and A B S Todd, Yorkshire, David Walker and Alwyn Wharton, Owens.

Part II.—E. M Ashcroft and F. H. S. Ashworth Owens; H. M. Berry, University; A. T. Blease, Owens; R N. Butterworth, Yorkshire; J. B Cook, R. D Fletcher, J. E Floyd, James Hindshaw, and H L. Jenkins, Owens; J. A. Johnson, University; C. P. Lapage and H. F. Lee, Owens; W. L. Maccormac, Yorkshire, H S.

breathing area. Over-eating also affects respiration by its influence on the heart: by its stimulating action on the splanchnic circulation it stimulates the respiratory movements, and it may further augment these movements by disturbing the action of the heart and hindering the movement of the blood through the lungs. Respiration is affected by over-eating in yet another way, one which seems to have been overlooked: every particle of food which is absorbed and does not go to increase the weight of the body and is not eliminated unkatabolised, as sugar or albumin, has to be *burnt off within the organism, and this very soon after* absorption. Now this combustion of food requires oxygen and one of the products of combustion is carbonic acid. It follows from this that the larger the amount of food ingested and absorbed the larger is the demand for oxygen and the larger the quantity of carbonic acid produced—in other words, the greater the respiratory interchange and the more ample the respiratory movements. The application of these facts in the treatment of dyspnœa will be referred to in its proper place.

Evils due to Faulty Metabolism either in the Digestive Tract or in the Tissues.

Before discussing these it will be well to trace the career of the redundant food through the body. When a redundancy of food is taken an excess of nutritive ingredients is absorbed into the blood; some—e.g., albumin and sugar—may pass out by the kidneys unchanged, but, except in disease, this only occurs after large surfeits, some may be stored, but it is only in the case of fat that this takes place to any extent, the capacity of the organism to store proteid and saccharide being very limited; in many individuals even the fat-storing capacity is small; in all the limit is reached sooner or later. It is, therefore, evident that dealing with individuals in the aggregate only a small proportion of the total excess of absorbed food is stored.

What then becomes of the excess which is neither stored nor passed out of the body unchanged? The reply is, it is katabolised—i.e., the organism is put to the profitless task of burning off the excess of fuel with which the body fluids are charged, the fats and saccharides being converted into carbonic acid and water and the proteids into these and likewise into urea, uric acid, kreatin, and allied compounds. This extra katabolism takes place chiefly in the muscles.

Does it not seem strange that the organism should be put to all this labour? Theoretically the most perfect arrangement would be for just so much food to be absorbed from the alimentary tract as is needed, but, though when an excess of food is ingested *absorption is less complete than with a bare* sufficiency, far more than the needful quantity is nevertheless absorbed. It is not surprising that the organism should possess some capacity for absorbing nutriment beyond the needs of the moment. All animals are liable to experience seasons of dearth, and it is of advantage that they should be able in times of plenty to absorb food beyond present requirements, and so store up supplies for future contingencies. It is, however, not so easy to explain why after this provision has been made the capacity to absorb an excess of food should still continue. Nature has apparently made no provision against a chronic *embarras de richesses* in the matter of food, and instead of altogether *refusing to absorb* a quantity of nutriment in excess of present and future needs, or, after having absorbed it, simply running it out unchanged, she goes through all the labour, not only of absorbing, but of katabolising the redundancy.

We may perhaps explain this apparent anomaly by the fact, already referred to, that under primitive conditions animal organisms are little liable *habitually to over-eat. But* whatever the explanation may be, certain it is that the animal organism is not only capable of absorbing a redundancy of nutriment, but, having done so, goes through the laborious process of katabolising it. This stands out as one of the most remarkable facts in the physiology of nutrition. For observe what this redundant katabolism implies. We are apt to lose sight of the fact that every katabolic change is attended by an unlocking of energy; hence redundant katabolism implies a wasteful expenditure of energy. What form does this surplus energy assume? The reply is that it takes the form of heat. All, or practically all, the energy of the organism manifests itself either as work or as heat, most *of the former* being converted into the latter within the body and passing off from it as such; thus all the "internal work" (movement of the heart, &c.) of the body is converted into heat and when a person is resting the whole of the energy unlocked by katabolism is dissipated in this way. From this it follows that all the energy set free by the redundant katabolism resulting from over-eating leaves the body as heat[4] and that the larger the amount of food absorbed the greater is the amount of heat given out. Gourmands, therefore, must emit more heat than spare-eaters and this involves either scantier clothing or increased evaporation from the skin and lungs. As a matter of fact *big eaters are generally big sweaters.*

There is yet another aspect from which we may view this superabundant katabolism with its corresponding evolution of energy. Just as chronic starvation leads to lack of energy, producing listlessness and apathy—Mr. Bumble, it will be remembered, well knew that the half-starved inmates of his union had *little stomach* for fighting—so, conversely, chronic over-eating is apt to cause trouble by leading to an undue accumulation and evolution of energy in the body, and in such cases the surplus energy may seek outlets in abnormal ways, such as in fits of irascibility and hysterical convulsions. The desire of the irascible man to break the furniture and of the hysterical woman to scream and rush wildly about must surely be exaggerated by the storage of an excess of energy in the body. I do not want to over-estimate this as an exciting factor—other factors, such as toxæmia, play their part—but it must certainly be conceded that surplus energy is apt to find an abnormal outlet. If a well-fed horse is not taken out to exercise he will kick his stable down and over-fed prisoners may, by the very fact of their being over-fed, be incited to insubordination. These considerations suggest that when an individual has a tendency to convulsive seizures we must be careful to keep his diet within due bounds.

We have now to inquire whether the redundant katabolism of the large eater is the same in kind as the katabolism which is not redundant.

There are strong grounds for assuming that when a large excess of fuel has to be katabolised the end-products are not quite the same as when only a sufficiency is taken. The excess is in the main katabolised by the muscles while in a state of quiescence; it is not, i.e., worked off in the katabolism which issues in muscle contraction. Whatever fuel is thus katabolised *does not constitute part of the* excess, inasmuch as it is used up in the performance of a normal function to which it is essential. Now, it is probable that the waste products of a muscle at rest are not altogether the same as those of a contracting muscle; possibly they are not so completely oxidised and they would appear to be more toxic in character, hence, the absorption of an excess of food not only leads to the production of an excess of poisons, but of poisons more than usually toxic. And this brings me to another point.

Evils due to Toxæmia.

There can be no doubt that the most serious results of over-eating are brought about by blood-poisoning or, as we now call it, "toxæmia." The extra katabolism which over-eating induces leads to an excess of poisonous waste-products, and it is probable, as we have just seen, that many of these are more toxic than are those which are formed when the food is kept within normal limits. Over-eating further tends to cause toxæmia by setting up indigestion. *There is no* sharp dividing line between normal digestion and indigestion; as with all other functions there are innumerable grades of efficiency,[5] and it goes without saying that digestion is more likely to reach a high grade of efficiency when a mere sufficiency of food is taken than when the quantity is excessive. Now the more efficient the powers of digestion the fewer are the poisons produced in the alimentary tract and *the less their* absorption into the blood. It is, therefore, manifest, and I cannot too strongly insist on the fact, that if we desire to keep down the toxicity of the blood we should zealously guard against excesses in eating.

The toxæmia of over-eating induces a multitude of evils, the chief of which we now proceed to consider.

Inflammation.—If not the sole, certainly by far the most potent, cause of inflammation is *chemical* irritation. It is difficult to point to a single instance of inflammation in which this factor can be eliminated from causation. We now know that the most violent mechanical injury, such as the cut of the surgeon's knife, does not cause it in the absence of pathogenic micro-organisms, and, further, that the inflammation due to micro-organisms is wrought by the toxins which these emit. Probably most cases of inflammation are due to toxins thus arising. In other cases the toxins causing inflammation are furnished by tissue metabolism, as in the pleurisy and pericarditis of Bright's disease, or they may be introduced as such into the body, as in the case of corrosive, alcoholic, and arsenical poisoning. When we total up all the cases of inflammation induced in one or other of these ways we find that for all practical purposes we have exhausted the list.

---

[4] The energy leaving the body as work cannot be regarded as redundant.

[5] See the writer's paper, "On the Gradations of Health and Disease," St. Bartholomew's *Hospital Reports*, vol. xxx., p. [illegible]

Gastritis and *enteritis* may be placed first among the many toxic inflammations due to over-eating. Over-eating by disturbing digestion leads to an undue formation of toxins, which by their direct action set up inflammation in the lining membrane of the alimentary tract. A familiar instance of inflammation thus induced is the condition known as consumption of the bowels met with among children, especially the children of the poor in large towns. It is essentially a toxic enteritis, and, though it results from errors in the quality rather than in the quantity of food I mention it here as it admirably illustrates some of the worst toxic evils resulting from dietetic errors. We are all familiar with these cases; the abdomen is large and flatulent and the motions are slimy, malodorous, and, it may be, bloody. Examine a child who has been suffering for some time in this way and we shall soon satisfy ourselves that his general condition is as much due to toxæmia as to starvation; sufficient food may be absorbed, but nutrition is perverted by the action of irritant poisons. The child is ill-grown and anæmic; the skin is thin, the eyelashes are long and silky, and the complexion is often wondrously like that observed in empyæma, in which disease there can be no doubt about its being due to toxæmia, disappearing as it does as if by magic upon evacuation of the pus. Treves in his work on Struma contends that the majority of the children presenting the so-called strumous diathesis are not the victims of a specific congenital habit but are simply delicate. With this view I entirely agree, and I make bold to add that the delicacy in these cases is essentially an acquired condition, the result in the main of defective feeding leading to toxæmia. If we give a child plenty of sunlight and fresh air, which tend to keep the body generally and the digestive organs in particular, in a healthy state, and feed it on a diet which is correct as to quality but insufficient in quantity, we shall tend to get starvation, pure and simple, without toxæmia, but the condition in this case is very different from that with which we are so familiar as occurring in consequence of a dietary which induces a high degree of toxæmia.[6] I have referred to these cases of enteritis because they show how grave and extensive are the evils which may result from toxæmia induced by dietetic errors.

Let us now revert to the toxæmia caused by gluttony. This may set up inflammation in any part of the body, either directly, or indirectly by lowering the resistance of the tissues to bacterial invasion. In gouty bronchitis, or the bronchitis of children suffering from consumption of the bowels, the toxic action is direct. As an instance of indirect action tuberculous inflammation may be cited. We have seen that the strumous diathesis may result from alimentary toxæmia which causes a diminished resistance on the part of the tissues to the attack of the tubercle bacillus, and I have little doubt that mercury which has long been known to be useful in struma does good by combating intestinal toxis. A more striking instance of the indirect action of such toxis in promoting inflammation is shown by its effect on suppuration, now known to be due to the action of specific (pyogenic) cocci. One of the first things to be done in all cases of actual or threatening suppuration—e.g., mammary abscess or stye in the eye, is to administer a purge; and, indeed, it may be said that in all inflammations one of our chief aims should be to diminish gastric and intestinal toxis.

Toxæmic inflammations are, of course, most frequent where the toxins are most abundant and, as we should expect, the poisons are most abundantly met with in the organs of elimination, whither they speed in their effort to escape from the body. This they do by all the surfaces communicating with the exterior. We are too much in the habit of thinking of the poisons as being eliminated almost exclusively by the skin and kidneys, but the fact is they get out wherever they can—by the skin, the kidneys, and the mucous lining of the alimentary, respiratory, and genito-urinary tracts. We know that drugs may be eliminated from all these regions and the same is true of the toxins of disease. We are all familiar with laryngitis, bronchitis, nephritis, cystitis, urethritis, gastritis, and dermatitis, of gouty origin, and we recognise that they are produced by the poisons of gout, but do we sufficiently realise that there are multitudinous other poisons capable of exciting similar inflammations? Here I may refer to the fact that when once inflammation has been excited by toxins it tends to persist apparently after the toxins have been eliminated, the inflamed areas thenceforth appearing to possess a peculiar attraction for the toxins. How otherwise are we to explain such a case as the following? A man who for years had suffered on and off from arthritic gout suddenly developed bronchitis; thereafter his arthritis disappeared once for all, while the bronchitis continued on and off till his death. The presumption is that the gouty poisons set up bronchitis and that the inflamed bronchial surface thenceforth attracted the poisons which found a ready exit in the abundant bronchial secretion, thus relieving the arthritic phenomena.

Cardio-vascular disturbances.—The toxæmia of over-eating may produce functional disturbances in the heart and arteries, such as palpitation and vaso-motor irregularities, but the chief way in which it affects the cardio-vascular system is by increasing peripheral resistance. This it does by constricting the systemic arterioles, apparently with the object of increasing the urinary flow so as to relieve the toxæmia, the intra-renal arterioles remaining in all probability dilated.[7] As a result the pressure rises in the systemic arterioles, the whole systemic arterial tree, together with the left side of the heart, being subjected to increased strain which eventuates in thickening and degeneration of both. Thus it comes about that the cardio-vascular system wears out sooner in the gourmand than in the spare feeder. Many are the dangers which beset the path of the habitual gourmand, but perhaps the greatest are those pertaining to the cardio-vascular system: he often dies from a prematurely worn-out heart or from the rupture of a miliary aneurysm.

Degenerations.—The toxæmia of over-eating may lead to degeneration in connexion with the inflammations and cardio-vascular changes just considered. It may also induce degenerations apart from these: the constant soakage of the tissues with toxins injures the delicate protoplasm, which thus tends to degenerate prematurely, its place being taken by fibrous tissue. Thus over-eating materially hastens that fibroid encroachment which is a natural senile change. As we should expect, the liver and the kidneys are especially apt to suffer; chronic over-eating causes chronic engorgement of the former organ and imposes upon it an amount of work far in excess of its powers; it also increases the work of the kidneys and exposes them to constant irritation by the toxins which are perpetually passing out through them.

Gout.—Over-eating is one of the chief causes of gout which is essentially a toxæmia. My own impression is that this disease originates in the digestive viscera and that uric acid is not the essential poison at work in it; but, be this as it may, it is certain that errors of diet play an important part in its causation. These errors do not merely pertain to kind, but to quantity. We are too much in the habit of simply telling our patients to avoid this and that without insisting upon the importance of keeping the total quantity of food within proper limits.

Nervous disorders.—The toxæmia of over-eating may set up a variety of nervous disturbances, such as headache, giddiness, tinnitus, irritability, depression, drowsiness, lassitude, numbness, flushings, pains about the body, weakness, or even partial paralysis of muscles; while neuroses of all kinds—epilepsy, angina pectoris, asthma, &c.—tend to be aggravated by it.

Age in relation to Over-eating.

We have next to consider the effects of over-eating as influenced by age, for, as hinted earlier, the element of age comes in here and has an important bearing on the issue. In youth there is greater capacity to deal with excess of food than in old age; the organs of digestion and excretion are then most vigorous and metabolism generally is most active, the vital fire burning fiercely, so to say, while the restless activity of the muscle system not only diminishes the likelihood of chronic excess, but also helps to mitigate its evils. In old age, on the other hand, there is a growing tendency to quiescence of the muscle system, side by side with a waning in digestive and excretory vigour and an increasing sluggishness of metabolism generally, the vital fire no longer blazing, but glowing and flickering rather and standing in danger of being extinguished altogether by the accumulation of its ashes. Yet at this very time we may find the individual *more than ever addicted to the pleasures of the* table and with an appetite and capacity for enjoying food altogether in excess of his requirements, being ever lured to his destruction. I am by no means certain that the use of artificial teeth by the old is an unmixed blessing. It may do harm by encouraging them to eat more food than is good for them and of a kind unsuited to their years. It is noticeable that almost all the old people who live to a great age in country villages—and it is here they reach the greatest age—rely on their *toothless gums, and the absence of teeth in the very old* may possibly be an indication to a return to the more simple diet of childhood.

---

[6] It seems to me that rickets is essentially a toxæmia of gastro-intestinal origin.

[7] See letter written by the writer to THE LANCET, June 8th, 1901, p. 1627.

We see, then, that the evils of over-eating are greatly influenced by age. During the period of growth, with a reservation to be considered directly, and even during early adult life, they are comparatively insignificant; it is in middle life that they generally begin to show obtrusively, thereafter becoming more and more insistent with every advancing year. We may sometimes see an old *man* of sedentary habit—old *women less frequently err in this* respect—whose appetite and enjoyment of food survive amid the general decay of his physical powers, loading his poor old stomach with the same quantity of food and alcohol as he consumed in the heyday of his active manhood, and expecting his stomach, liver, and kidneys, after some three score or more years of overwork, to achieve the same metabolic feats as in their prime; and generally with this result, that he is a curse to himself as well as to those around him. It is true that some can eat abundantly into extreme old age without much apparent harm, but such cases are exceptional. Almost all of Humphry's centenarians were moderate eaters; he tells us that the great proportion of old people are reported "*to have been moderate or small eaters, to have taken* little alcohol, and commonly not much meat."[*] I cannot too emphatically impress upon my readers the desirability—nay, the necessity—of keeping the aged on a spare diet. Do not let us extinguish the flickering fire of age by piling on too much fuel.

I have said that with one reservation the young are little liable to suffer seriously from chronic over-feeding. The exception is in the case of infants. I have been long convinced that they are often greatly over-fed, and quite recently Dr. Eric Pritchard has contributed a valuable paper dealing with this important subject. I believe that infants in this country suffer much more from an excess than from a deficiency of food. In the first place the food given them is in a highly concentrated form, consisting of almost pure proteid, starch, and sugar, with very little unabsorbable material; and it is, moreover, administered in a liquid or pappy form which allows it to pass with a fatal facility into the stomach. The modern infant is often in fact, much in the position of the far-famed Strasburg goose. At a period of life when it is a stationary animal and prevented from working off an excessive dietary by abundant muscular activity (which same activity is but too often still further limited by *unsuitable* clothing) its digestive organs are burdened with an excess of highly concentrated foods, with results most disastrous to the helpless victim.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

(Concluded from p. 1492.)

CHEMISTS and druggists were not so largely represented this year in the Queen's Hall exhibition as on previous occasions and several of those exhibiting presented many articles besides drugs for inspection. Many interesting specimens were on view on the stall of Messrs. Cooper and Company, of 80, Gloucester-road, South Kensington, S.W. The aerated mineral waters containing both oxygen and carbonic acid gas are worthy of special mention. Great pains, as we have shown, are taken to secure the purity of these waters, special apparatus for the distillation of water being devoted to the purpose. Lithia, piperazin, magnesia, and urotropin are amongst the special drugs to be obtained dissolved in "oxycarbonated" water. The exhibit included also some neat cachets for inclosing drugs. Mr. W. Martindale, of 10, New Cavendish-street, W., showed a number of useful analytical appliances for clinical purposes besides a great number of medical preparations and special drugs. Ovo lecithin in the form of pills, confection, and injection was exhibited by Billon's Ovo Lecithin Company, of 16, Water-lane, Great Tower-street, E.C. As we have already pointed out, ovo lecithin has been administered with encouraging results in debilitated conditions. Hommel's hæmatogen we have dealt with in our analytical columns in which we pointed out that it contained *pure hæmoglobin with the entire unaltered salts of the blood* plasma. The preparation was exhibited by Messrs. Nicolay, of 36 and 36A, Saint Andrew's-hill, E.C. Messrs. Coxeter and Company, of 4 and 6, Grafton-street, Gower-street, W.C., showed apparatus for the production of anæsthesia by nitrous oxide gas, ether, and chloroform with special accessories. The exhibit included apparatus for the administration of oxygen and an ozone generator. Specimens of "iron milk," upon which we have quite recently reported in our analytical columns, were shown by the British Iron Milk Syndicate, Limited, of Savoy House, 115 and 116, Strand, W.C. Iron milk is a liquid containing pyrophosphate of iron in suspension. Messrs. Arthur and Company, of 69, Berners-street, W., exhibited a number of special preparations which we have noticed on previous occasions. The double salt of gold and arsenic known as "bromaurum" made by this firm is well known. Messrs. Rebman, Limited, of 129, Shaftesbury-avenue, W.C., besides medical publications, exhibited serum preparations and glycerinated calf lymph. The stall of Messrs. F. Newbery and Sons, of 27 and 28, Charterhouse-square, E.C., was well stocked with a number of special pharmaceutical preparations. Amongst these were a useful series of granular effervescent salts and the special prepara*tions of Messrs. W. R. Warner and Company.*

The food section was largely comprised of milk and milk products. The Aylesbury Dairy Company, of St. Petersburgh-place, Bayswater, W., exhibited a number of interesting preparations, including humanised milk, sterilised milk and cream, and milk specially adapted for the needs of the young child. Similar preparations were exhibited by Messrs. Welford and Sons, of Elgin-avenue, Maida Vale, W., who make a speciality of asses' milk. Concentrated milk was the subject of exhibition by several well-known firms, such as the Anglo-Swiss Milk Company, of 10, Mark-lane, E.C., and Mr. Henry Nestlé, of 48, Cannon-street, E.C., the latter exhibiting also a special food for infants.

The best example of a food prepared from milk is *plasmon*, which *contains* the physiologically unaltered proteid of milk. Its nutritive value is well known. Many food preparations containing plasmon were also shown on the stall of this company (International Plasmon, Limited, 56, Duke-street, Grosvenor-square, W.). Messrs. Cosenza and Company, of 95, Wigmore-street, *Cavendish-square*, W., exhibited the well-known Maggi soup cartridges for the use of troops, the exhibit including also a consommé and a tonic bouillon. Peptenzyme in many forms containing the digestive secretions of the digestive glands was the feature of the exhibit of the Peptenzyme Company, Limited, 80, Gloucester-road, South Kensington, S.W., but they also exhibited zymocide, described as a non-poisonous antiseptic for surgical and general use. "Marvis" is one of the best examples of a dried fish food. It makes a good nourishing soup and is prepared by the Marvis Company, of 7, Eastcheap, E.C. Proteno was amongst the first preparations of milk proteid made and it has been used with advantage as a food and for raising the nitrogenous content *of farinaceous foods*; the preparation was exhibited by the Proteno Company, Limited, of 38, Welbeck-street, W. Meat preparations were represented in great number and variety on the stall of Bovril Limited, of 152 to 166, Old-street, City-road, E.C., while Messrs. G. Nelson, Dale, and Company, *of* 14, *Dowgate-hill*, E.C., exhibited their now well-known mutton essence called "hipi," the New Zealand native word for sheep, pronounced "heapy." The Liebig Extract of Meat Company, Limited, of 9, Fenchurch-avenue, E.C., exhibited Lemco, a highly-concentrated beef preparation, and Oxo, representing both the nutrient and stimulating properties of beef. The Hovis

---

[*] Old Age, George Murray Humphry, M.D., F.R.S., 1889, p. 14. See also p. 51 for some striking observations on the same subject.

Bread Flour Company, Limited, of Macclesfield, exhibited their recently-introduced foods for infants and invalids. We have so recently described these foods in our analytical columns that we need offer no further remark. Special foods for diabetic patients and for use also in obesity were exhibited by Messrs. Callard and Company, of 65, Regent-street, W., and the Myosin Albumin Meat Extract Company, of 107, Strand, W.C., submitted their preparations containing a very high proportion of pure myosin albumin which is, of course, highly nutritious.

There was a fair display of surgical and hospital appliances, amongst those exhibiting being Messrs. Maw, Son, and Sons, of 7 to 12, Aldersgate-street, E.C.; the Holborn Surgical Instrument Company, of 117, Holborn, E.C.; Messrs. Maple and Company of Tottenham Court-road, W.; Messrs. Wodderspoon and Company, of Gate-street, Lincoln's Inn Fields, W.C. (temperature and other charts); Mr. W. K. Stacy, of 19, Newgate-street, E.C. (nurses' instruments); Messrs. F. Davidson and Company, of 140, Great Portland-street, W. (sight-testing apparatus); and in this category might be included the natural shaped boots of Mr. Thomas Holland of 40, South Audley-street, Grosvenor-square, W. These boots are so made as to prevent the inner and outer lines of the soles from converging to a point beyond the space between the second and third toes. Thus the boots, while not ugly in appearance, are adapted to the natural shape and lines of the feet.

ERRATUM.—The "eucryl" preparations described in our article last week were exhibited by Eucryl, Limited, and not by Messrs. Major as stated.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THE nineteenth annual meeting of this society was held at 11, Chandos-street, London, W., on May 15th, under the presidency of Dr. F. DE HAVILLAND HALL, chairman of the Executive Committee.

Dr. HALL, in his remarks, said that, as on previous occasions, they had an excellent report to give to the members. The new business had been exceedingly good; they had had 133 proposals, against 114 in the previous year, and there had been 28 proposals for additional benefits, against 22. Though their members had increased he was thankful to say that the sickness claims had been less than in the previous year—£7829 10*s.*, as against £8250. In the annuity fund there was a small increase and a small decrease in the life assurance fund. As the members were aware, the society was doing no further business in these two branches, but the Rock Life Assurance Company allowed a rebate of 5 per cent. to members of the society who effected assurances with them. He thought that taking out in this or some other life assurance company an annuity payable at the age of 65 years was a preferable way of meeting a difficulty rather than extending their sickness limit beyond the age of 65 years, as had been suggested: an annuity payable at 65 years of age would be a certainty, whereas sickness allowances after that age must necessarily be altogether uncertain. The economy of management of the society still continued. During the past year the management expenses had been less than 5 per cent of the premium income, as against 10 per cent. which was allowed by the rules. They had put by over £1000 to the management reserve fund and they had made the large increase of £1346 4*s.* 6*d.* in their investment reserve fund which now stood at £7979 9*s.* 3*d.* The total funds of the society had also grown considerably—viz., from £143,552 11*s.* 3*d.* to £154,353 17*s.* 3*d.*, an increase during the past 12 months of upwards of £10,000. The votes of the society in connexion with the Royal Medical Benevolent College had this year been given to Gerald MacNaught, the son of a deceased member, and from the position which the boy held at the last election he (the Chairman) hoped that the votes would ensure his election into the school at Epsom on this occasion. He had great pleasure in announcing that Sir William Church, President of the Royal College of Physicians of London, had consented to act as arbitrator should they elect him. The record of committee attendances would show how well the affairs of the society were looked after by the members of the committee, and he thought that it would be impossible to get a body of men to work more harmoniously than they had done. In Mr. Harber, who, he was glad to see, was present that afternoon, they had an excellent man of business, and he felt that as long as he audited the accounts the financial condition of the society would be well looked after, and, lastly, he would like to express on behalf of the committee its high appreciation of the manner in which the secretarial work had been done.

A motion, proposed by Mr. R. J. BRYDEN, seconded by Dr. N. BATEMAN, that the report of the Committee and the audited accounts for the year ending Dec. 31st, 1901, be received and adopted, was carried.

The officers for the ensuing year were then elected.

Dr. ST. C. B. SHADWELL said that before they concluded their meeting he should like to propose a vote of thanks to the chairman for the way in which he had conducted the affairs of the society. As a member of the Executive Committee for one year he had had the pleasure of seeing the way in which Dr. Hall had conducted the business at their monthly meetings, and he was sure that every member of the society must feel much obliged to Dr. Hall for what he had done and be pleased on that occasion to express their confidence in him and to thank him for the trouble which he had taken.—Mr. J. BRINDLEY JAMES, in seconding the motion, spoke of the valuable help and assistance which Dr. Hall had rendered to the society.

The motion was carried with acclamation.

Dr. HALL said that he was obliged for their kind expression of opinion. As he had said in his opening remarks, it would be impossible for a committee to work together more harmoniously than that committee had done; its members had sometimes come to a division but they had always agreed on the line to be pursued. He could only hope that in the future, as in the past, they might continue to work together in the same pleasant manner. He was much obliged to them for re-electing him again as the chairman.

Looking Back.

FROM

THE LANCET, *SATURDAY, MAY 29,* 1824.

IT is stated that "heat is the *lightest body* known; therefore it always has a tendency to ascend." We would rather say that *heated particles* of any matter whether of a solid, liquid, or æriform become specifically lighter by expansion, and therefore will rise when heated in a medium consisting of particles of similar specific gravities with themselves; as for instance, when some of the particles of water are warmed in a medium of similar particles, these heated particles will rise through those that are not so; and thus we find that hot water always rises to the surface of a vessel of cold. The particles of air which are heated in the atmosphere, always ascend and fly upwards, because they are expanded by the heat, and therefore rendered lighter than those around them, but if atmospheric air be heated and thrown into a volume of hydrogen gas, they will not rise, nor will the "heat ascend": simply because the heated particles of atmospheric air remain still specifically heavier than the hydrogen gas. So also, notwithstanding hot water rises to the surface of cold, yet it will not rise through the atmosphere, unless, indeed it be so far expanded as to be converted into steam or vapour, in which case it is found to be specifically lighter. We may fairly conclude that in every case where heat appears to ascend, that it is not a property of heat itself, or the levity of its nature, but that it simply expands either the particles of some liquid, or air, which become specifically lighter than they were before, therefore rise upwards and carry the heat which they have acquired along with them; therefore, instead of saying that "heat is the lightest body known," we may with more propriety observe that heated particles of common matter are lighter than cold ones.

We are particular in exposing these errors, because they mislead the followers of truth and injure the true interests of science by impressing false notions on the mind, which are carried with all their baneful effects into every inquiry and prejudice, as we every day see, even the results of experiments themselves.[1]

ROYAL ACADEMY OF MEDICINE AT PARIS.

Sitting of the 24th of February.—M. RULLIER presented to the Academy a stomach from the internal surface of which, twenty-four fungi projected. These excrescences existed in the mucous membrane, and were formed out of it.

The Secretary read, in the name of M. JULIAN FONTENELLE, the case of an individual who had only one kidney. Occupying its usual situation, this kidney was five times larger than in the healthy state.

Sitting of the 20th.—M. RICHERAND occupied the time of the meeting with an account of an operation for strangulated femoral hernia, in which he had an opportunity of proving the excellence of the instrument commonly called COOPER's hernia knife, although the president of the meeting M DUBOIS had publicly used it fifteen years before the English surgeon published a description of it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7474 births and 4757 deaths were registered during the week ending May 24th. The annual rate of mortality in these towns, which had been 17·2 and 17·3 per 1000 in the two preceding weeks, declined again to 16·7 per 1000 last week. In London the death-rate was 16·4 per 1000, while it averaged 16·8 in the 75 other large towns. The lowest death-rates in these towns were 8·2 in Smethwick, 9·1 in Croydon, 9·2 in Reading, 9·5 in East Ham, 10·3 in Walthamstow, 11·2 in Rotherham, 11·3 in Bootle, and 11·4 in Newport (Mon.); the highest rates were 22·1 in Gateshead, 22·5 in Hanley, 23·0 in Liverpool, 23·9 in Burnley, 24·1 in Barrow-in-Furness, 24·2 in Rochdale, 24·4 in Merthyr Tydfil, and 26·4 in Oldham. The 4757 deaths in these towns last week included 531 which were referred to the principal zymotic diseases, against 489, 519, and 516 in the three preceding weeks; of these 531 deaths 157 resulted from measles, 119 from whooping-cough, 66 from diphtheria, 56 from diarrhœa, 51 from scarlet fever, 47 from small-pox, and 35 from "fever" (principally enteric). In Croydon, Willesden, Brighton, Devonport, and six other smaller towns no death from any of these diseases was recorded last week; while they caused the highest death-rate in Tottenham, Liverpool, Wigan, Burnley, Barrow-in-Furness, Bradford, and Tynemouth. The greatest proportional mortality from measles occurred in Bournemouth, Southampton, Plymouth, Grimsby, Oldham, Barrow-in-Furness, Bradford, and Rhondda; from scarlet fever in Walsall, Aston Manor, and Bolton; from whooping-cough in Liverpool, Bootle, Barrow-in-Furness, South Shields, and Tynemouth; from "fever" in East Ham; and from diarrhœa in Wigan. The mortality from diphtheria showed no marked excess in any of the large towns. 47 fatal cases of small-pox belonging to these towns were registered last week, of which 24 belonged to London, eight to Tottenham, eight to West Ham, two to East Ham, two to Swansea, and one each to Leyton, Birmingham, and Tynemouth. There were 1344 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, May 24th, against 1443, 1419, and 1360 on the three preceding Saturdays; 307 new cases were admitted last week, against 250, 248, and 233 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2222, 2212, and 2207 at the end of the three preceding weeks, had risen again to 2236 at the end of last week; 280 new cases were admitted during the week, against 258, 256, and 270 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 240, 231, and 216 in the three preceding weeks, rose again last week to 237, but were 11 below the corrected average number. The causes of 54, or 1·2 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Bolton, Bradford, Leeds, Hull, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Aston Manor, Liverpool, St. Helens, Warrington, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·1 and 19·4 per 1000 in the two preceding weeks, further increased to 20·3 per 1000 during the week ending May 24th, and showed an excess of 3·6 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·3 in Leith and 14·1 in Perth to 22·4 in Paisley and 22·5 in Glasgow. The 656 deaths in these towns included 16 which were referred to measles, 14 to whooping-cough, 14 to diarrhœa, six to scarlet fever, three to "fever," one to small-pox, and one to diphtheria. In all 55 deaths resulted from these principal zymotic diseases last week, against 46 and 74 in the two preceding weeks. These 55 deaths were equal to an annual rate of 1·7 per 1000, which was slightly below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been nine and 21 in the two preceding weeks, declined again last week to 16, of which five occurred in Edinburgh, three in Dundee, three in Paisley, three in Perth, and two in Glasgow. The deaths from whooping-cough, which had been 16 and 25 in the two preceding weeks, decreased again to 16 last week and included five in Glasgow, five in Aberdeen, and two in Dundee. The fatal cases of diarrhœa, which had been 23, 13, and 19 in the three preceding weeks, declined again last week to 14, of which seven were registered in Glasgow, three in Aberdeen, and three in Greenock. The deaths from scarlet fever, which had been two, four, and one in the three preceding weeks, rose again to six last week, and included three in Glasgow, where the fatal cases of small-pox also was registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 113 and 114 in the two preceding weeks, further increased last week to 156, and were 55 above the number in the corresponding period of last year. The causes of 21, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·6 and 24·8 per 1000 in the two preceding weeks, declined again to 19·1 per 1000 during the week ending May 24th. During the past four weeks the death-rate has averaged 22·9 per 1000, the rates during the same period being 16·2 in London and 17·2 in Edinburgh. The 139 deaths of persons belonging to Dublin registered during the week under notice were 41 below the number in the preceding week and included six which were referred to the principal zymotic diseases, against nine, 12, and 13 in the three preceding weeks; of these, two resulted from measles, two from scarlet fever, one from "fever," and one from diarrhœa. These six deaths were equal to an annual rate of 0·8 per 1000, the zymotic death-rates during the same period being 1·9 in London and 1·1 in Edinburgh. The fatal cases of measles, which had been three, six, and three in the three preceding weeks, declined to two last week. The mortality from scarlet fever was slightly in excess of that recorded in recent weeks. The 139 deaths in Dublin last week included 25 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the numbers in the preceding week, while those of elderly persons showed a slight decline. Four inquest cases and four deaths from violence were registered; and 62, or nearly one-half, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon A. Kidd to the *Collingwood*. Staff Surgeons: H. E. South to the *London*; E. P. Mourilyan to the *Retribution*; H. Elliott to the *Severn*; A. Maclean to the *Penguin*; and R. Hill to the *Tribune*. Surgeons: E. F. Power to the *Pactolus*; H. W. B. Shewell to the *Surprise*; and H. O. Adams to the *London*.

ARMY MEDICAL STAFF.

Surgeon-General Alexander F. Preston, K.H.P., is placed on retired pay. Dated April 23rd, 1902.

---

[1] Some editorial observations expressing dissent from the then existing theory of heat.

Lieutenant-Colonel J. E. Fishbourne is appointed to the medical charge of the Military Prison at Woking.

Royal Army Medical Corps.

Colonel W. Donovan, C.B., now in South Africa, is appointed Principal Medical Officer at Hong-Kong.

Lieutenant Craig is appointed for duty in the North-Western District, and Lieutenant Cotterell to Bulford Camp, Salisbury Plain.

Royal Army Medical Corps (Militia).

Surgeon-Lieutenant Herbert Fox, from the 2nd Hampshire Royal Garrison Artillery (Volunteers), to be Lieutenant, and to be seconded for service in South Africa.

Royal Army Medical Corps (Volunteers).

The Manchester Companies: Lieutenant C. E. Preston resigns his commission.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Cheshire and Carnarvonshire: The undermentioned Surgeon-Captains to be Surgeon-Majors: A. M. Archer and R. L. Jones. 1st Hampshire: Surgeon-Lieutenant E. N. Close to be Surgeon-Captain.

Rifle: 1st (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant J. E. B. Wells to be Surgeon-Captain. 2nd Volunteer Battalion (the Prince Albert's Somersetshire Light Infantry): Surgeon-Lieutenant W. Thompson to be Surgeon-Captain. 3rd Volunteer Battalion the Gloucestershire Regiment: Charles Robert Browne to be Surgeon-Lieutenant. 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry): Surgeon-Captain E. Lee to be Surgeon-Major. 2nd Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant J. Ratcliff Gaylard resigns his commission. 19th Middlesex (St. Giles's and St. George's, Bloomsbury): The undermentioned Surgeon-Lieutenants to be Supernumerary whilst serving with the Bearer Company of the 5th London Volunteer Infantry Brigade: J. G. Fraser and J. J. R. Macleod.

South African War Notes.

Lieutenant Beatty, R.A.M.C., is reported out of danger.

Civil Surgeon White was reported very slightly improved on May 27th.

The steamship *Nubia* left Port Natal for England on May 24th with the following invalids on board:—Captain L. E. L. Parker, R.A.M.C., and Civil Surgeons Ilott and Hoops. The following members of the Army Medical Service are also on board: Lieutenant-Colonel R. L. Love, R.A.M.C., Lieutenant C. S. Cato, R.A.M.C., and Civil Surgeons Macdonald, Ellis, and Heron.

The Report on the Education and Training of Officers of the Army.

Notices of this report have appeared in the daily and service journals but no copy of the report has, so far as we know, yet been issued from any official or authorised source. If the analyses which have appeared correctly summarise its nature and contents it seems to be a document of a severely critical and trenchant kind and to put forward a series of recommendations which, if adopted, will bring about a radical reform. It is in the Royal Military College, Sandhurst, and the system in force there, together with an alleged lack of supervision, that the committee apparently finds so much to condemn; the Royal Military Academy, Woolwich, appears to have passed through the inquiry satisfactorily.

Deaths in the Services.

Surgeon-Colonel Samuel Archer, A.M.S. (retired), at Rapallo, Italy, aged 68 years. He joined the army as Assistant-Surgeon in 1858, became Surgeon in 1873, Surgeon-Major in 1873, Brigade-Surgeon in 1887, and retired eight years later. He served with the 101st Fusiliers in the campaign in the North-West Frontier of India in 1863 (medal), including the storming of the Conical Hill and destruction of Umbeylah (medal with clasp). In the Nile Campaign 1884–85 he was in charge of the field hospital at Korti (medal with clasp and Khedive's star). He was in medical charge at Wady Halfa and of lines of communication to Akasheh in the expedition on the Soudan Frontier in 1885–86.

Examiners for the Indian Medical Service.

The Secretary of State for India has appointed the following gentlemen to be examiners for the Indian Medical Service: Professor Clifford Allbutt, F.R.S. (Medicine and Therapeutics); Mr. Howard Marsh (Surgery and Diseases of the Eye); Professor D. J. Cunningham, F.R.S. (Surgical Anatomy and Physiology); Professor R. Calder Leith, F.R.S. Ed. (Pathology and Bacteriology); Dr. R. Milne Murray, F.R.S. Ed. (Midwifery and Diseases of Women and Children), Professor Ralph Stockman, F.R.S. Ed. (Chemistry, Pharmacy, Botany, and Zoology).

Surgeon-General Townsend, C.B., A.M.S.

This officer, who it will be remembered was severely wounded at Tweebosch, will, it is understood, soon take up his duties. He has been principal medical officer with Lord Methuen's force, with which he did much hard and excellent service, since the war began, having embarked from England with the staff of the 1st Division.

The Royal Military Tournament.

The Royal Military Tournament at the Agricultural Hall, Islington, will close its doors on June 5th. The entertainment as a whole shows this year a great improvement on those of previous years and no one who is able to visit the Tournament should fail to do so.

The annual Ambulance Challenge Shield Competition of the Volunteer Medical Association will be held this year at the Guildhall on June 7th, at 3 o'clock. The honorary secretary of the association, we are informed, has arranged with the officer commanding the London companies of the Royal Army Medical Corps (Volunteers) for the board and lodging at their headquarters, Calthorpe-street, Gray's Inn-road, of squads coming from the provinces for the competition. Further information can be obtained from Surgeon-Major J. J. de Z. Marshall, honorary secretary, Shortwood, Teddington, S.W.

The report by the Central British Red Cross Committee on Voluntary Organisations in Aid of the Sick and Wounded during the South African War has been issued in the form of a Blue-book. It consists of some 200 foolscap pages and contains several well-executed plans and photographs.

Inspector-General Sir Henry F. Norbury, Director-General of the Royal Navy Medical Department, will be present at the Sanitary Institute coronation dinner on June 2nd at the Midland Grand Hotel.

Correspondence.

"Audi alteram partem."

THE WILLIAM SMYTH MEMORIAL FUND.

To the Editors of The Lancet.

Sirs,—Would you kindly allow me the courtesy of the columns of The Lancet to enable me to thank the medical profession for their great kindness to me and my family in connexion with Dr. Smyth's death? My heart is too full of gratitude for me adequately to express my feelings and I can only say I shall never forget the generosity of my dear husband's colleagues in the affliction that so suddenly came upon us. I use the columns of The Lancet as the most effective means of reaching the medical profession.

I am, Sirs, yours sincerely,

Burton Port, co. Donegal, May 26th, 1902. E. M. Smyth.

WHAT IS SCROFULA?

To the Editors of The Lancet.

Sirs,—I have pleasure in answering the query of your correspondent "Pes" in The Lancet of May 24th, p. 1498, as to the reason why "scrofula" is retained in the new official list of causes of death, a copy of which appeared in a recent number of The Lancet. The reason is that the term "scrofula," as distinct from tuberculosis, is in common use by medical men, not a few of whom (including certain physicians and surgeons of eminence) still believe the conditions which these terms imply to be distinct. Without presuming to dogmatise on the question I may perhaps quote in justification of my conduct the following remarks by Professor Clifford Allbutt in his "System of Medicine," vol. iv., p. 597: "Whether scrofula is always due to the tubercle bacillus or always associated with it is not yet decided. It seems probable that scrofula may arise by the agency of microbes other than tubercles; again, that, originating independently of tubercle, on it tubercle may afterwards supervene, and, once more, that scrofula may be due to tubercle primarily, or even exclusively No doubt these problems will soon be settled." Having regard to the foregoing considerations and to the fact that the term "scrofula" has appeared in the list of diseases used in this office ever since its establishment I was unwilling to discard it, lest the comparability of figures in a series of years should be impaired. "Pes" will, however, probably perceive that as soon as unanimity on the subject is attained by the medical authorities it will be easy, if requisite, to add together the two lines affected in the tables for previous years, and thus nothing will be lost.

I am, Sirs, yours faithfully,
JOHN TATHAM

General Register Office, Somerset House, May 27th, 1902.

ETHER v CHLOROFORM.

To the Editors of THE LANCET

SIRS,—I, like many others, have read with great interest in THE LANCET of May 24th, p. 1457, the record by Mr H Challice Crouch and Mr Edred M. Corner of their investigation into the effects of ether inhalation on the respiratory organs It is impossible to do so without a strong feeling of admiration for the thoroughness and perseverance with which they have gone into the matter It is difficult for anyone who has not undertaken a somewhat similar investigation fully to realise the great calls on time and patience which they must have met with. The result is, they tell us in brief, that they found that out of 2400 ether cases 10 developed more or less severe chest symptoms, one case ending fatally, and we are left to conclude, presumably, that out of 24,000 cases 100 would develop similar troubles and 10 would become defunct. In short, we are asked to reconsider our position, to look upon chloroform as a less noxious body than ether, all things considered, and consequently fitter for routine employment in anæsthetic practice. Before so concluding are we not entitled to ask Mr Crouch and Mr Corner, as a favour to the profession and for the sake of suffering humanity, to continue their investigations for another year—with this alteration. Let the house officers and anæsthetists use $CHCl_3$ in the 2400 cases and ether in the 600, or in like proportion, and then we may be in a better position to judge as to results.

Mr Crouch and Mr Corner remark that the death rate under $CHCl_3$ *is said to be* 1 in 3000 It *is* said to be—and who orginally arrived at this conclusion I do not know One enthusiast has even put the death rate as low as 0 in 40,000. I submit, however, that were the results of every large general hospital in the United Kingdom during any given year investigated there is not one at which the death rate from $CHCl_3$ would not work out higher than 1 in 3000 In this year's official report of one large institution (which shall be nameless) six deaths are stated to have occurred in 2901 administrations of $CHCl_3$, = 1 in 483. In this hospital very little ether is used Further, at another institution of similar size, during a recent year 12 deaths were recorded from $CHCl_3$ and these chiefly occurred in cases chloroformed in or off the wards (as Mr Crouch and Mr Corner describe) by house surgeons. The house surgeons are now positively forbidden to use $CHCl_3$ in such cases unless quite unavoidable. One could say a good deal more, but *cui bono?* This question has been hammered out for the past 50 years and one might with as much profit enter into a discussion on the respective merits of spring mattresses and feather-beds.

Mr Crouch and Mr Corner mention that "anæsthetists never hear at all of the subsequent history of their cases." I think that this can be true only of a proportion of cases, but, at any rate, if an appreciable percentage of patients in private practice—or for that matter in hospitals—did get bronchitis or pneumonia after ether it is impossible to suppose that anæsthetists would not hear of it, and very plainly, too, from the surgeons in charge. The strongest proof of the greater safety of ether for routine cases, taking *all* things into consideration, seems to be the fact that almost invariably as the experience of anæsthetists increases they use ether, or some mixture chiefly consisting of it, more widely And can we suppose that any sane man would spend his day going from house to house with a bag containing the necessary ether and gas impediments, weighing anything from 10 to 20 pounds unless he had overwhelming proof that he was thus enabled to use an agent many times safer than the very portable chloroform?

In Germany operating theatres are kept at a very much higher temperature than in this country, generally speaking, and bronchitis is seen there after ether, $CHCl_3$, or cocaine anæsthesia not uncommonly[1] It is obviously due to the sudden change of temperature in the patient's surroundings when taken back to the ward The greater the change, evidently the more bronchitis. The practical point arising out of this paper by Mr Crouch and Mr Corner is, Can we not possibly minimise this change of temperature by keeping the operating theatres at a reasonably warm temperature and the wards as near as is practicable the same? and also prevent a chill in the draughty corridors by extra warm blankets and covering the patient's head with a towel?

Those whose faith in ether has become somewhat perturbed by the resuscitation of the "bronchitis bogie" can scarcely do better than read Dr R. J Probyn-Williams's admirable paper on the Use and Abuse of Ether in the *Edinburgh Medical Journal* for May, 1902.

I am, Sirs, yours faithfully,
THOMAS D LUKE,
Instructor in Anæsthetics University Wards Royal Infirmary, Edinburgh

Edinburgh, May 27th, 1902.

INFANTILE SCURVY AND RICKETS

To the Editors of THE LANCET

SIRS,—In reference to the letter of Dr Clement Dukes in THE LANCET of May 10th, p 1358, allow me to point out that although medical men have been strenuously advocating the boiling of milk and the restriction of the baby's food to boiled milk and cooked milk foods, still the diet of very few children indeed has been [so restricted, nevertheless, the evil consequences of such a restriction have been prevented by the all but universal habit which the working- and middle-classes have of feeding their children with little bits of anything and everything from their own tables

Two years ago, however, I had a child under my care who was fed absolutely on artificial food and boiled milk. She was born in the early spring, was a delicate and fretful little thing, and even although the greatest care was bestowed on the preparation of this food she had frequent attacks of diarrhœa. She got on fairly well between these attacks through the summer and by the sixth month she had cut two teeth and seemed in moderate health but always fretful and subject to diarrhœa. She showed no signs of rachitis, such as sweating, &c. About the eighth month, however, severe symptoms of scurvy appeared, hæmorrhage from the bowel, bleeding gums, extravasation of blood into ankle-joints, &c. Here was a condition where the cause was apparent and by way of experiment I simply ordered the mother to procure fresh milk three times a day and give it to the child in the fresh and unboiled state, this was all the treatment adopted, with the exception of small doses of solution of hydrochlorate of morphia to relieve the pain, and it proved eminently satisfactory

Other three cases of infantile scurvy have come under my notice in the course of the past eight years. In each the symptoms were sufficiently pronounced to prevent their being mistaken and in each raw milk proved efficacious treatment. Rachitis and infantile scurvy may and do undoubtedly occur together but they also may and do as undoubtedly occur independently Infantile scurvy yields readily to anti-scorbutic treatment. Rachitis is much more resisting, in its treatment the diet should certainly be such as would preclude the merest possibility of scurvy—antiscorbutic if you like, but that is not in itself sufficient by any means Generous diet, fresh air, &c, all sometimes fail to produce any marked effect. The various preparations of iron, too are all valuable adjuncts in the treatment of rickets Scorbutic disease has always been amenable to treatment, but in rickets the elimination of scorbutic phenomena is but a small part of the treatment

It seems to me that with the universal adoption of prepared foods and the general call for the sterilisation of milk in the artificial rearing of children has come a recrudescence of scurvy The detection of scorbutic phenomena in children—considered apart from the knowledge of the potency of these new foods to produce such—gave infantile scurvy an exaggerated importance Not only was its appearance misunderstood but it seemed in many quarters to be tacitly assumed that the secret causation in the problem of rickets was this, infantile scurvy.

---

JOHN SUTHERLAND, M.B., C.M., B.Sc. Edin.
Netherfield, Notts, May 24th, 1902.

TROPICAL ABSCESS OF THE LIVER.

To the Editors of THE LANCET.

SIRS,—In your report of the discussion which followed the reading of Mr. Godlee's paper on the above subject at the meeting of the Royal Medical and Chirurgical Society on May 13th, published in THE LANCET of May 24th, p. 1467, my remarks are so imperfectly given that I must ask you to allow me to make the following corrections.

I did not say that "it was the practice in India to use Dieulafoy's aspirator and in small abscesses this was sufficient." What I said was that "it was *at one time* (30 years ago) the practice in India to use Dieulafoy's aspirator, and *in a certain proportion* of cases, *especially* in small abscesses, this was *sometimes* found to be sufficient and no further surgical interference was necessary." I did not say that "even in larger abscesses one or two such operations were sufficient." I said that they were *sometimes* sufficient and quoted a series of successful cases of this kind published by Lawrie a few years ago. The usual practice in India has been to remove a portion of rib when necessary and to cut down directly into the abscess and to drain freely, but a preliminary operation of stitching the liver to the abdominal wall has been generally considered impracticable, and unnecessary on account of the innocuous character of liver pus in acute cases and because the large drainage-tube, occupying entirely as it does the incision into the liver, effectually shuts off the abscess cavity from that of the abdomen and in 24 hours the path is sealed by adhesions if they did not already exist.

I am, Sirs, yours faithfully,
A. CROMBIE, M.D. Edin.
Beckenhall-mansions, W., May 23rd, 1902.

ON THE USE OF THE TERM "BLASTOMA."

To the Editors of THE LANCET.

SIRS,—In the report of the meeting of the Pathological Society of London of April 29th, given in THE LANCET of May 3rd, p. 1249, which has just come to hand, I note that, following Dr. C. P. White, the term "blastoma" is employed to indicate the group of tumours formed of "indifferent cells" which eventually give rise to both connective tissue (sarcomatous) and epithelioma (carcinomatous) elements—the carcino-sarcomas. If I remember aright, Dr. White first employed the term as thus defined in his article upon the Definition, Terminology, and Classification of Tumours in the *Journal of Pathology*, vol. vi., 1899, p. 220. In his interesting Erasmus Wilson Lectures delivered in February last and published in your pages, he again urged the employment of the term in this same sense, and in both articles he states that he owes it to Dr. Herbert Snow, who in November, 1895,[1] proposed its use to indicate a somewhat similar group of new growths. What Dr. Snow suggested was that one variety of "round-celled sarcoma" should be given this name, forms of "congenital cancer, so to speak," arising in such parts and in such circumstances "as to leave no doubt as to their origin from unobliterated rudiments of fœtal structures." Under this title, according to him, would be grouped "many lesions occurring for the most part in childhood or early youth—the ovary, palate, mediastinum, bladder, prostate, &c.," and "consisting wholly or almost so of rounded cells."

It will be seen in the first place that Dr. White in seizing upon Dr. Snow's term, employs it in a different sense. Dr. Snow's definition is vague and his classification, I fear, cannot stand. There would thus be at least a plausible excuse for the appropriation, were it not that years prior to Dr. White and several years also prior to Dr. Snow this term had been introduced in a more definite sense and by a very prominent pathologist—in fact, by no less an authority than Professor E. Klebs, in the second volume of his frequently quoted Algemeine Pathologie, published at Jena in 1889. For some 330 pages in his treatment of the subjects of tumours he consistently employs the term and so important is his work that there is no excuse for overlooking his usage thereof or for employing it without acknowledgment in a sense different from that laid down by him.

Briefly, Professor Klebs objected to confining the term "neoplasia" to tumour growths on the ground that simple hyperplasia is also neoplasia. For "neoplasia" and "neoplasm" he substituted "blastosis" and "blastoma," and he classified tumours into the two great groups of the blastomata, or tumours proper, subdivided into typical and atypical, and the teratoblastomata, or teratomata, the products of fœtal implantation.

I am, to some extent, personally interested in this matter because in recent articles (as, for instance, in that upon the Causation of Cancerous and other New Growths, published in the *British Medical Journal* and the *Yale Medical Journal* last year), reverting to Professor Klebs's classification, I have used the term blastoma in the sense indicated by him. A little consideration will show that it is essential to possess some word to designate everyday tumours as distinct from the peculiar group of the teratomata and that this term "blastoma" is quite the most suitable for the purpose. I had imagined that Professor Klebs's work was so well known that it was unnecessary to indicate the origin of the word; evidently this was a mistake, but evidently also when it has been given so clear a meaning there is no justification for seeking to send it into more active circulation with a new and restricted significance. Priority demands that in the absence of urgent cause it be employed as originally understood and that Dr. White select some other term for the group of cases of carcinoma-sarcomatodes.

I am, Sirs, yours faithfully,
J. GEORGE ADAMI.
Montreal, May 15th, 1902.

THE FUTURE OF THE ROYAL ARMY MEDICAL CORPS.

To the Editors of THE LANCET.

SIRS,—Since the new Royal Warrant and also the rules for admission into the Royal Army Medical Corps have been published, in which most of us agree that the changes are distinctly for the better, it may not be out of place to put before your readers and more especially intending candidates for commissions into the corps certain points which to my mind are paramount in importance and about which up to the present the Government has published no definite order. 1. The extent of increase of *personnel* in the corps. 2. The facilities to be given for "study leave," especially with a view to promotion examinations and "specialist" work. 3. The equalisation of home and foreign service. 4. The proportionate rates of pay in India as compared with those at home along with charge pay and other allowance when serving in that country.

The first of these, "the extent of increase of the *personnel* in the corps," is the most important, as without an increase from the present number of medical officers, some 970 up to 1400 or 1500 now that South Africa has to be manned, the points enumerated in No. 2 and No. 3 will be *impossible* to carry out. As this is a matter of money it will be the chief stumbling-block to the home Government. With regard to No. 4, dealing with pay in India, if the corps is to attract young medical men the Indian Government must give way, as no young doctor who understands the matter would care to have to serve in the Indian climate with less advantages than he has at home. If Mr. Brodrick wishes to make the Royal Army Medical Corps the best army medical service in Europe, as he has said he does, and I am sure intends to do his best to do, the points I have upheld must be acceded to and the competition for the corps would, I am persuaded, be a steady and lasting one. On the other hand, it must be clearly understood by those casting in their lot with the army doctor that promises are sometimes like pie-crusts and that we must get at least these concessions in black and white before the Royal Army Medical Corps *does* become the best army medical service in Europe.

I am, Sirs, yours faithfully,
VERAX.
London, May 18th, 1902.

WHAT IS THE BEST PORTABLE SPRAYING DISINFECTING APPARATUS?

To the Editors of THE LANCET.

SIRS,—I shall feel greatly obliged if any of your readers will favour me through the medium of THE LANCET with their views as to the best portable spraying disinfecting apparatus for use by sanitary inspectors.

I am, Sirs, yours faithfully,
M.O.H.
May 29th, 1902.

PLAGUE PRECAUTIONS AT MARSEILLES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from page 1500.)

The Rats on the "Sénégal."—Anti-plague Serum Inoculations.—The Ministerial Instructions in regard to the Destruction of Rats.—New Measures for placing Rats in Quarantine.—The Various Means of destroying Rats.—The Bacteriological Examination of Rats.

As already explained, the occurrence of cases of plague on board the *Sénégal* distinctly demonstrated that the means of disinfection employed were inefficient. The *Sénégal* came from Beyrout. She had called at Alexandria and then sailed for Marseilles, reaching the latter port on August 28th, 1901. The crew then numbered 85 men and there were 254 passengers. The ship was provided with a disinfecting stove and there was a surgeon on board. Everybody was in perfect health, nevertheless 409 trunks, boxes, and the like, were disinfected at Frioul. All the personal linen, table-linen, and bedding were passed through the stoves and exposed to the action of superheated steam under pressure. In fact everything was done that could be done with the exception that no measures were taken in regard to the rats that might be on board. The crew remained at Marseilles for 17 days, they were examined before the ship sailed again, and were in perfect health at the moment of their departure. The *Sénégal*, with its 174 scientific explorers and excursionists, went first to Corsica, but four days later, on leaving Ajaccio to proceed eastwards to Palestine and other places of interest, one of the crew fell ill with plague. This occurred on Sept. 18th. The ship had left Alexandria, the last port where there were cases of plague, on August 23rd, and it was four days later that she reached Frioul and that the process of disinfection was commenced. There were no cases of plague at Marseilles and 27 days had elapsed since the ship had left Alexandria before the first case of plague occurred. There was, however, some doubt as to whether the patient was really suffering from plague. The passengers were at first kept on board the ship. Four rats were captured and bacteriologically examined. By the time these rats were proved to be infected a second case of plague was notified on board the *Sénégal* and the symptoms of the first case had so developed as to leave no doubt as to the nature of the disease. Thus we find a ship that has been disinfected and on board of which on starting for another cruise everyone seemed to be in good health, although subsequent bacteriological examination proved that the rats in the ship were infected with plague. Then occurred two cases of plague, not among the passengers but among the members of the crew, who, by reason of the work which they have to do, are brought more in contact with the rats than are the passengers. In most other European ports the passengers and crew would have had to remain on board till the termination of the period of quarantine. They would then have continued in contact with the rats that seem to have been the cause of the cases of plague that had occurred. In this instance the passengers were at least able to land and had houses to live in. Thus separated from the rats no further mischief occurred, the only trouble being that at Frioul there were not attendants enough to see to the comfort of so unexpected and numerous an advent of first-class passengers. The *Sénégal* arrived at Frioul on a Wednesday at 11 o'clock in the morning. By 5 o'clock on the following Saturday afternoon everyone on board who desired to take this precaution had been inoculated with the anti-plague serum. This would have been done more rapidly but for the facts that some time elapsed before the presence of plague was absolutely proved and that the passengers insisted on the employment of fresh serum which had to be telegraphed for from Paris.

The rule at Marseilles is to keep a reserve of 400 doses of anti-plague serum and whenever any of these are employed a further supply is ordered. A large portion of this stock had been exhausted to inoculate the crew of the *Laos*, which arrived at Frioul shortly before the *Sénégal* The serum, protected by the air-tight tubes in which it is placed, is supposed to retain all its qualities for about a year, therefore it was not necessary to ask for fresh serum, though this was obtained. But there is no law by which crews and passengers can be compelled to submit to inoculations. If, on this occasion, there was no resistance this was due to the eminent *savants* who were on board the *Sénégal*, for they were the first to set the example by submitting themselves to the process of inoculation. Only eight or nine persons refused

The great question, however, which the adventures of the *Sénégal* excursionists serve to bring prominently forward is that of the rats. The importance of dealing with the rats was, it is true, fully realised by the sanitary authorities before the occurrence of plague on board the *Sénégal*; but there is always a broad dividing-line between what is theoretically proclaimed and what is practically enforced The *Sénégal* incident occurred in September, 1901. In July, 1899, the following ministerial instructions had been issued to the port sanitary authorities: "Rats and mice are very active agents in the propagation of plague. When they are affected the disease soon spreads among the populations where they dwell or pass. The epizootic among these animals generally precedes by a few days the human epidemic. Therefore we must at all cost prevent their presence on board ships or at the quarantine stations. When a ship is in harbour the ropes or chains by which it is anchored or lashed to the shore must be armed with brushes, discs, or other contrivances which will prevent rats climbing along these ropes for the purpose of either leaving or of penetrating into the ship. During night-time the gangways to the shore must be removed. Before the ship is loaded care must be taken to see that there are no rats on board. If there are any rats they must be destroyed in the following manner. The ship, while empty, must be disinfected with sulphurous acid in all those parts that are frequented by the rats. The other parts of the ship may be disinfected with saline sublimate solutions, one gramme of bichloride of mercury to two grammes of marine salt mixed in one litre of distilled water. The dead rats must be cremated. The sanitary *régime* to be imposed upon the ships depends on the perfect execution of these instructions. The more thoroughly and rapidly the rats are destroyed the less will it be necessary subsequently to enforce these measures."

Had the above instructions been strictly carried out with regard to the *Sénégal* the pleasure-cruise on which it started would probably not have been brought to so premature and unpleasant a conclusion. As a matter of fact, it is only within the last six months that these instructions have been strictly applied, and this has involved quite a revolution in the procedure adopted in regard to the ships arriving from infected ports. To describe in a few words the procedure now enforced, it may be said that, though human beings are no longer put in quarantine when all on board are in good health, a strict quarantine is always put upon the rats. When a ship arrives from an infected port the hold is locked up. The passengers and crew having been medically examined and the linen and bedding having been disinfected, the ship can then proceed from Frioul to Marseilles Thus, so far as the passengers are concerned, there is only a delay of a few hours—that is, of course, if all are well on board. But the ship, though allowed access to the Marseilles docks, is placed in a sort of quarantine and has to fly the yellow flag This flag signifies that the rats have not yet been examined and that all ropes and cables attached to the ship must be fitted with contrivances that will prevent the rats from running along them to get on, or off, the ship The hold is then searched and if any dead rats are found this is thought to be a suspicious circumstance. If no dead rats are found traps are set to capture live rats. The specimen rats thus secured have to be handled with care The method adopted is to soak a cloth in a mercurial solution and to take hold of the rats with this moist cloth. The rats are then bacteriologically examined. If the rats are found to be suffering from plague the ship is generally sent back to Frioul so as to be disinfected more thoroughly, in which case, of course, all the rats are killed. Nor is this precaution confined to the ships. The rats on shore, in and about the docks, are constantly hunted and when captured, examined. On one occasion these land rats were found to be infected. The dock was therefore at once condemned and closed to all traffic. A great rat-hunt was organised, all the rats were killed, and all the merchandise that happened to be in the dock at the time was disinfected. Of the rats captured on 44 ships from January to March this year in seven of these ships they were found to be suffering from plague. This clearly shows the usefulness and the necessity of the precautions taken. So far, and in most cases, the rats were killed by means of sulphurous fumigations Altogether 10,611 rats have been killed in the three months. These figures give some idea of the importance and extent of the work done. But there are serious objections to the employment of sulphurous fumes. This process does not kill the rats at once. They have time to hide themselves and it is very difficult to find their bodies. If they are not found then decompositon ensues and a very serious nuisance is created. Moreover, the shipowners complain that the sulphur injures the ironwork of the ships and also some of the goods on board. For these reasons the use of carbonic acid gas is preferable. But it is much more difficult to apply this method. The carbonic acid employed is in bottles and in a liquid condition. When liberated it produces a freezing temperature, whereas the normal temperature should be maintained so that the gas may spread itself in all directions and sink to the bottom of the hold where the rats mostly congregate. Experiments are now being made to warm the gas as it leaves the bottle by discharging it into a tube and making it pass through hot water. Then precautions must be taken to clear the hold before allowing any men to enter. For this purpose two ventilating shafts of uneven length are introduced, one as an air inlet and the other as an outlet. To hasten the process a fan should be employed to draw out the air. Then candles are lowered into the hold and no one is allowed to descend unless the candles burn brightly. All this, however, is still only in the experimental stage. Nor can it be said that the problem has been solved in all its details. For instance, the rats on board a French ship may all be destroyed and everything rendered secure but this ship may be moored next to a foreign ship where no such precautions have been taken and the French ship is then invaded by rats from the foreign ship. Even if the same process were applied to every foreign ship entering a French port there is no telling what would happen to these ships when they went to other countries and to other ports?

It is with regard to the workers below deck that the principal danger arises. They come in personal contact with the rats. This is more especially the case with natives who, from religious motives, insist on cooking their own food. The fragments of this food attract the rats and they overrun the bunks These men often catch and handle the rats and thus expose themselves to a serious risk of infection. Most of the cases of plague that have occurred on board ship have been among the crew and those members of the crew who work below deck. This is a fact which tends to confirm the theory that the rats constitute the main danger. This is so evident that one of the main difficulties in dealing with the passengers of the *Sénégal* when they were landed at Frioul was due to their refusing to be waited upon by the stewards and stewardesses of the ship. They insisted that the chief advantage of being landed at Frioul was that they might be separated from those who had been exposed to the greatest danger of infection. Although the extra attendants hastily recruited at Marseilles were quite incompetent the passengers preferred the consequent inconvenience. They felt safer when their beds were made and their food was served by persons who came from Marseilles and had not been living among the infected rats of the ship.

From all these details it will be seen that a new departure has been made. The experiments now being carried out on a very extensive scale by Dr. Catalan, the able and experienced port sanitary officer of Marseilles, will be watched with deep interest, especially in all maritime countries. I must not conclude this description of the good and instructive work done without expressing my thanks to Dr. Catalan for his unfailing courtesy, for the facilities which he gave me to visit the disinfecting station at Frioul, and for the very important information which he enabled me to gather. Imitation is the sincerest form of flattery, and I think that in several respects Dr. Catalan will find many imitators.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

(Concluded from p. 1428.)

Photo-therapy.

PROFESSOR BIE (Copenhagen) read a paper on the Use of Light in the Treatment of Disease according to Finsen's Method. He first explained the action of light on the skin, the blood, and the nervous system, as well as the effects which it produced on metabolism. Light, he said, was able to destroy bacteria in the superficial layers of the skin but it did not penetrate to the deeper layers of the skin, so that a direct destruction of tubercle bacilli in the lungs was obviously impossible. Photo-therapy was of much utility in small-pox, for under red light the pustules showed a tendency to dry up and suppuration was diminished. In erysipelas also the extension of the disease seemed to be restrained by the action of light, but in scarlet fever and measles the effect was less marked. The good effects of light in the treatment of disease depended not only on the exclusion of injurious forms of light but on the intensification of rays which had a beneficial influence on morbid processes. Red and ultra-red rays produced thermic effects, violet and ultra-violet rays produced chemical effects, and yellow and green rays were neutral. Electric light contained a smaller proportion of chemically active rays than did sunlight, so that it required to be concentrated by lenses. Professor Bie then described the apparatus devised by Professor Finsen. In the treatment of lupus two square centimetres of skin were exposed to the rays for an hour every day, the result being that the diseased portions were replaced eventually by scar tissue. The exposures had sometimes to be repeated. The treatment was painless but relapses occasionally occurred. The therapeutic action of light had proved successful not only in lupus vulgaris but also in lupus erythematosus, alopecia areata, acne vulgaris, acne rosacea, and nævus.

In the discussion it was stated that unqualified practitioners had opened establishments for the treatment of patients by Finsen's methods; this abuse, however, would probably receive a check when the medical profession recognised the merits of the treatment and recommended it in suitable cases.

Dr. **HOLLÄNDER** (Berlin) then described his method of treating lupus erythematosus, which is not a disease of tuberculous origin but is localised in the cutaneous glands. He had found that painting the part with iodine in conjunction with the internal administration of quinine had proved perfectly successful.

The Glycogen Reaction of Leucocytes.

Dr. **KAMINER** (Berlin) read a paper on the relations of this reaction to infectious diseases. His observations were made on animals inoculated with various cultures. He found that the reaction occurred in infections due to staphylococcus, streptococcus, pneumococcus, bacterium coli, bacillus anthracis, bacillus pyocyaneus, and the bacillus of enteric fever, but it failed to appear after injections of cultures of the organism of fowl cholera and the toxins of tetanus. The reaction occurred after injection of the toxin of diphtheria but not when the animal had been immunised.

Dr. **HOFBAUER** (Vienna) said that in the human subject the results were quite different from those just described, for patients suffering from infectious diseases did not show those reactions.

Uric Acid.

Professor **KLEMPERER** (Berlin) read a paper on the Solubility of Uric Acid. He said that the urine contained a larger quantity of dissolved uric acid than might have been supposed. He had found that the solvent action of the urine depended on the amount of urochrome (yellow colouring matter) which was present.

Charcot's Crystals.

Professor **GUMPRECHT** (Weimar) showed that these crystals might undergo coagulation. They therefore belonged to the albuminous class of substances but the nature of the albumin was not yet ascertained.

Glycosuria in Tramps.

Professor **HOPPE-SEYLER** (Kiel) read an interesting communication on glycosuria observed by him in persons who previously to their admission into hospital had suffered from insufficiency of rest and food. In 11 such cases he found that sugar was present in the urine to a small extent but it disappeared in a few days on the patients being properly fed. One man who had been admitted twice to the hospital showed this symptom on each occasion. The patients exhibited enlargement of the liver and Professor Hoppe-Seyler was of opinion that the glycosuria was due to pancreatic derangement. He proposed for this condition the name of "glycosuria of tramps."

Glycosuria and Diabetes.

Dr. F. **BLUM** (Frankfort) said that he had found that the administration of even a small quantity of the substance of

McLellan, William Parker, and C. A. Ricketts, Owens; E. E. Roberts, University; and George Taylor, Owens.

SECOND EXAMINATION.

A. *Anatomy and Physiology.*—Fred Bailey and F. P. H. Birtwhistle, Yorkshire; William Calverley, Catherine Chisholm, and Reginald Collier, Owens; W. B. Cooke, University; Catherine L. Corbett, G. D. Dawson, R. L. Ferguson, and Joseph Fletcher, Owens; B. R. Flint, Yorkshire; E. S. H. Gill, University; F. W. M. Greaves, Yorkshire; W. L. Hawksley and Pantland Hick, University; F. C. Hudson, E. E. Hughes, and Ernest Hulme, Owens; Lancelot Hutchinson and T L. Kenion, University; C. E. Lea, T. W. P. Leighton, J. T. R. MacGill, Hector Mackenzie, and H. B. Moore, Owens; G. C. Scott, University; James Smalley, J. F. Smith, Philip Talbot,* and Henry Thorp, Owens; Herbert Tomlin, Yorkshire; A. M. Walker, Owens; T. E. Walker and H. W. L. Waller, University; F. J. Walton, W. D. Wilkins, and J. S. Young, Owens.

B. *Materia Medica and Pharmacy.*—A. W. Byrne, University; Archibald Cambell and P. C Garrett, Owens; E. F. Hoare, University; S. E. McClatchey, Owens; S. W. McLellan and H. G. Thompson, University; S. H. West, W. A. Wheeldon, and H. V. White, Owens.

* Was awarded University scholarship.

ABERDEEN UNIVERSITY.—At examinations for the degrees of Bachelor of Medicine and Bachelor of Surgery the following candidates were successful in the subjects indicated:—

Medicine, Clinical Medicine, Surgery, Clinical Surgery, and Midwifery.—Louis Coetzee, *Lewis D. Cruickshank, Jas. B. Elder, Harry W. Elwell, *Robert D. Keith, Geo. B. Kiloh, Jeannie C. Macleod, Archibald Mahomed, James B. Rae, *Alex. C. Reid, Alex. Robertson, R. B. Robson, John S. Rose, Thos. S. Slessor, Jas. Soutter, and Alex. Watt.

Pathology and Medical Jurisprudence.—Frank W. Begg, *Hugh S. Brander, Richard G. Brown, †Alex. Callam, A. Dyce Davidson, William Elwood, James Farquhar, Maurice B. Johnson, *Alex. F. Macbean, Gordon W Maconachie, *G. G. Macdonald, William Macgillivray, John A McKenzie, †Hugh Maclean, Malcolm Macleod, †William A Mearns, Kenneth S. Melvin, Jas. E. Mennie, Andrew B. Morris, *W. F. Munro, *Stephen Niven, *F. G T. Peterkin, Frank L Pelly, James B. Rae, J. H. Shepherd, *F. K. Smith, William A. Smith, †William C. Souter, William Stewart, *George Stoddart, Cornelius A. Suvoong, *Arthur J. Watt, and William Alfred Watson.

Pathology.—William R. Pirie and George B. Sleigh.

Anatomy, Physiology, and Materia Medica.—Francis Anderson, William Anderson, *William Beedie, *William R. Catto, *Alex. Flett, James S. Gray, George Hall, John Hunter, Alex. Hutchison, Henry W. Jeans, *Francis H. Johnson, *Frederick L. Keith, Geo. E. Macallan, Malcolm Macleod, and John M. Taylor.

Anatomy and Physiology.—Catherine E. Anderson, John Anderson, James Clark, Francis W. Davidson, Alex. Duguid, Walter A. Elwood, Thos. C. Innes, Neil Kennedy, Helen McGlashan, Donald McKay, Charles G McMahon, Archibald D. Pringle, Michael B. H. Ritchie, Alex. N. Ross, Bertie R. G. Russel, Herbert W. B. Ruxton, Cyril M. Smith, and William Wood.

First Professional Examination (Botany, Zoology, Physics, and Chemistry).—Alex. Brown, Robert R. Duncan, Francis W. Falconer, Alex. D. Fraser, Alistair S. Garden, Chas. B. Gerrard, Stewart C. Howard, Cecil V. Impey, Alex. W. Laing, James M. Macdonald, *James Macintosh, Kenneth Mackinnon, *George Milne, *Benjamin Mitchell, H. R. Neilson, Gavin E A. Petrie, Arthur W. R. Pirie, John Proctor, Alex. Robertson, Paul B. Roth, Robert F. Russel, Jas. A. Scharenguival, Jas. Silver, Robert N. Thomson, and Isaac T. B. DeVilliers. The following have passed one half of the first professional:—Geo. Cooper, Alex. McR. Donaldson, Herbert W. Glashan, Alfred P. Hall, Neil P. Macphail, Jas. Raffan, David McD. Roger, Geo. E. Shand, Henry Smit, and Alex. F. Wallace.

* Passed with distinction. † Passed with much distinction.

The Diploma of Public Health (D.P.H.) has been conferred upon the following:—

E. Nash, M.B., Ch.B., The Holt, Hertfordshire; W. Bisset, M.B., Ch.B., Aberdeen; and F. Keyt, M.B., C.M., Ceylon.

MR. JOHN LLOYD DAVIES, L.R.C.P. Lond, M.R.C.S. Eng., was returned on March 25th as a member of the Newport Town Council.

MEDICAL MAGISTRATE.—Mr. Francis Richardson Cross, M.B. Lond., F.R.C.S. Eng., has been placed on the Commission of the Peace for the city and county of Bristol.

ANDERSON'S COLLEGE MEDICAL SCHOOL.—The winter session of Anderson's College Medical School was formally closed on April 1st when the prizes were distributed by Lord Provost Chisholm. There was a large attendance of students and of the public. Mr. A. Malloch Bayne, president of the school, occupied the chair. The Lord Provost briefly addressed the meeting and commented on the nobility and the beneficence of that field of effort and enterprise which the students had chosen as their future lot. They had already shown their high appreciation of it by the fact that they had made it the object of their choice; but they would allow him to say, as one drop in the great cloud of witnesses by which they were surrounded, that they who merely stood outside looked on with affection and admiration—affection for the men and admiration for the efforts and triumphs of those who were engaged in the fields of medical and surgical science and who had by their efforts and labours produced results so marvellous in themselves and had wrought such delightful achievements for the relief of the suffering and sorrows of the world.

INEFFICIENT VACCINATION.—In the course of an inquiry held at Bristol on March 25th into an application of the city council to the Local Government Board for sanction to borrow £44,266 for isolation hospital purposes the inspector (Mr. Arnold Royle, C.B., M.R.C.S. Eng.), on being informed by the medical officer of health that there was a great deal of one-mark vaccination in Bristol, observed that such vaccination was inefficient and only an imperfect protective against small-pox.

BROMSGROVE, REDDITCH, AND DROITWICH ISOLATION HOSPITAL.—The new isolation hospital for the combined districts of Bromsgrove, Redditch, and Droitwich was opened at Hill Top, Bromsgrove, on March 25th, by Mrs. Amphlett, wife of Mr. R. H. Amphlett, K.C., the chairman of the Joint Hospital Committee. The new building is the latest of several isolation hospitals which have been provided in recent years in different parts of Worcestershire on the initiative of the Worcestershire County Council, and it supplies a long-felt want in this part of the country. For many years the district medical officers of health of the three towns concerned have been urging the necessity for hospital accommodation for the isolation of infectious disease, but the heavy expenditure needed for building and maintaining a suitable hospital has always stood in the way of action by an individual sanitary authority. Some attempts at combination had been made, but it was not until the county council intervened in 1896 that practical steps became possible. In that year the county council, acting upon the powers given to them by the Isolation Hospitals Act of 1893, formed the three towns of Bromsgrove, Redditch, and Droitwich, together with the intervening rural districts, six sanitary authorities in all, into a combined area for the provision of a joint isolation hospital. An admirable site on high ground was secured at Hill Top, Bromsgrove, in 1897, and in June, 1898, a temporary hospital of wood-lined iron buildings and double-walled tents was opened for the reception of patients suffering from scarlet fever. This temporary hospital is still in use and has done excellent work, some 340 cases of scarlet fever having been treated with a mortality of 13 only. Plans for the permanent hospital were then prepared by Mr. Hare of London and the building was commenced in 1900. It consists of an administrative block containing the principal offices with ample accommodation for nurses, servants, and porter; four separate ward blocks and a sixth block containing a fully equipped laundry with drying cupboards, ambulance house, mortuary, and a seven-feet Thresh disinfector. Each ward block is divided into male and female wards, with nurse's room between, the largest for scarlet fever patients, the others for enteric fever, diphtheria, and doubtful cases respectively. The number of beds is nominally 40, the scarlet fever block containing 18, the enteric fever block 14, and the remaining blocks four beds each, but the cubic air space allowed for each bed is so great that an addition to this number, especially of children's cots, can easily be made. The cubic space provided is over 2500 cubic feet per bed in each block and in the smaller wards it is over 3000 cubic feet per bed. The population of the combined districts served by the hospital is 56,777.. The temporary hospital, having been used for over three years for cases of scarlet fever, is now to be transferred to another part of the district where it is to be erected and kept in readiness for the isolation of small-pox cases should the necessity arise.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARFORD, A. M., M.D., L.R.C.P., M.R.C.S., has been appointed Assistant Anæsthetist to the Royal Dental Hospital, Leicester-square.

BOYES, JANE, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Island of Coll, Argyllshire.

BOYLE, N. C., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health by the Penge Urban District Council.

BRISCOE, WILLIAM THOMAS, M.D., M.Ch. Dubl., has been re-appointed Medical Officer of Health of the Pewsham District by the Chippenham Board of Guardians.

the suprarenal gland caused glycosuria in animals and he recommended the making of investigations on the human subject for the purpose of ascertaining whether in diabetes there were anomalies of the suprarenal glands.

Dr. VOGT (Strassburg) read a paper on Glycosuria produced Experimentally by Means of Phloridzin.

Dr. BIAL (Kissingen) made some remarks on glycuronic acid, a product of the metabolism of sugar discovered by him in the intestines. When large quantities of the acid were present in the intestinal canal it was eventually absorbed and might be found in the urine. He then described the chemical conditions under which the acid was produced.

Graves's Disease.

Dr. GOEBEL (Bielefeld) described a case of Graves's Disease in which he had obtained a successful result by injections of blood serum taken from a goat the thyroid gland of which had been removed. He had also administered the milk of the animal to the patient.

Dr. BLUM (Frankfort) expressed the opinion that the success in this case was due principally to the milk diet; he had known recovery to follow the use of milk diet with exclusion of meat.

Thyroidin in Cretinism

Dr. SCHOLZ (Graz) gave an account of the use of thyroidin in cases of cretinism. The results were quite unsatisfactory, the patients becoming worse, so that the administration of the remedy had to be stopped. There was therefore a marked difference between the effects produced by thyroidin in cretinism and in myxœdema.

Professor NAUNYN (Strassburg) said that Dr. Scholz had been treating cases of endemic cretinism, but he (Professor Naunyn) had observed in *sporadic* cretinism an obvious improvement under the use of thyroidin compounds.

Among the many other papers submitted to the Congress mention may be made of those read by Professor MÜLLER (Munich), on Autolysis, by Dr. VON CRIEGERN (Leipsic), on Poisoning by Paraphenyldiamin; by Dr. LENNHOFF, on Traumatic Moveable Kidney; and by Dr. SCHRÖTTER (Vienna), on Actinomycosis of the Heart.

Next year the Congress will meet in Leipsic.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Decline of the Plague Epidemic.—Curious Natural History Facts in Gujerat.

THIS season's recrudescence of plague throughout India may now be said to be on the decline. After having reached nearly 25,000 deaths in one week the mortality has steadily fallen and for the past seven days 17,302 deaths have been returned, as against 19,412 for the previous report. For the corresponding week last year there were only 4093 deaths. The special features to be noted are the decline in the Punjab, the rapid fall in the United Provinces, and the steady decrease in Bengal. The recrudescence expected in Bengal has been abortive and there has been as yet no renewal in the Behar district. Plague, however, has at last spread to Eastern Bengal. This has so far been entirely free, but recently cases have occurred near Goalundo and also at Baritpur, a village in Mymensingh. The figures for the week are: Bombay city 587 deaths, the Province 1673, Karachi city 120, Madras Presidency 34, Calcutta 577, Bengal 653, the United Provinces 806, the Punjab 12,311, the Mysore State 124, Hyderabad State 154, Kashmir 428, and Berar 30. The outbreak in Calcutta is following an unusual course. It has not developed with such virulent outburst and it is more prolonged. In Bombay city also the disease is running a different course and there, too, it seems on the decline.

The province of Gujerat has lately been overrun with rats in enormous numbers. The young crops have been eaten up and great damage has been done. The excess has been amongst field rats, not amongst the town rats, and the extraordinary fact is that they have disappeared almost as rapidly as they came. Although plague is existent to a small extent in certain places this disease has not been the cause of their diminution. They have in reality been starved. There have been no crops in the fields except tobacco, castor, and aniseed, for none of which do they seem to care. There has been prolonged drought in this district also, and, whether due to this or to the excess of rats, there has been an almost total disappearance of snakes. Another association worth noting is the sudden exodus of quail. There is no evidence that the rats have died from plague or from any other form of septicæmia.

May 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Port Sanitary Authority: the Medical Officer's Annual Report.

DR. E. W. HOPE, who is medical officer of the port sanitary authority of Liverpool as well as medical officer of health of the city, has recently issued his port sanitary report for the year 1901. The report contains much information as to the health of the port during the past 12 months, also an explanation of the system under which the port sanitary authority is conducted and a number of valuable tables and charts. The port sanitary authority's district extends from Formby Point along the coast-line and the east side of the river Mersey as far south as a point just beyond Garston and Speke, it crosses the estuary to Ince on the Cheshire side of the Mersey and proceeds as far as New Brighton and Little Meols. The port sanitary authority is informed of the approach of vessels by telephone from the Formby lightship, a distance of 10½ miles. On arrival vessels are boarded and examined by the port sanitary medical officers. The work of the port sanitary authority administration is carried out in conjunction with the staff of the customs which renders valuable assistance. Aid is also given by the regulations of the Mersey Docks and Harbour Board, of the London and North-Western Railway Company in connexion with Garston Docks and of the Manchester Ship Canal. Manchester-bound vessels infected with cholera, yellow fever, or plague are dealt with under an Order of the Local Government Board by the Liverpool Port Sanitary Authority. The medical staff of the port sanitary authority in ordinary circumstances consists of the medical officer of health and two deputy medical officers, one of whom is on duty during each tide. Four inspectors thoroughly conversant with marine matters are employed exclusively in routine port work, and in the ordinary inspection of ships. They also carry out the fumigation and disinfection of ships. The removal of patients from ships and the disinfection of bedding, clothing, &c., are carried out by the city staff of the Health Committee in all cases, and this staff also assists, when necessary, in the disinfection of vessels. With regard to hospital accommodation, the city hospitals are, as a rule, used for the reception of all sea borne cases of infectious disease, whilst cases which require to be dealt with under the Local Government Board Order are taken to the port hospital on the Cheshire side of the river. Instructions relating to infectious diseases and printed in some half a dozen languages are given to the *Liverpool Steamship Owners' Association* and to the various shipping firms for use amongst their captains. They are also distributed to the foreign consuls. The report also contains instructions guarding against the spread of plague. During the past year the actual number of cases of infectious sickness, other than cholera, yellow fever, and plague, landed from vessels arriving at the port of Liverpool was 84, as against 101 in the preceding year. There was an increase in the cases of typhoid fever, of which there were 27 cases, as against 23 in the preceding year; and of scarlet fever of which there were six, as against five in the preceding year. 18 cases of small-pox were landed from vessels, as against 25 in the preceding year. There was one case of plague, whereas three were landed in 1900. It is also interesting to note that 28 cases of phthisis were reported as occurring on ships arriving at the port. Thorough fumigation of the berths occupied by the patients was carried out in all cases.

The Royal College of Physicians of London.

Dr A. F. S. Grünbaum, the assistant lecturer in chemical physiology at University College, has been appointed by the Royal College of Physicians of London Goulstonian Lecturer for the ensuing year.

The Lancashire Asylums Board.

At the recent quarterly meeting of the Lancashire Asylums Board which was held at Preston Mr. Jenkins moved the adoption of the report of the Additional Accommodation

Committee. Since the last meeting of the board the committee had visited seven sites, only one of which was considered suitable—that situated at Whalley. A discussion arose on the necessity of providing further asylum accommodation in the county palatine. The subject was not considered as urgent by some members who argued that there was room now at all the four asylums and at Winwick for 600 or 700. The chairman, however, pointed out that the committee must not lose sight of the fact that it took five or six years to build an asylum. The difficulty of obtaining sites was a growing one. The committee had had such outside pressure put upon it that he should be sorry if it was to relax its efforts. It was not at all probable that the small county boroughs would construct asylums. If Liverpool intended to do so it would require one on as large a scale as that at Winwick. Mr. Shelmerdine said that a strong feeling existed in Liverpool with respect to the cost to the city of its lunatics. Many members of the city council felt that they were being unjustly mulcted. It had just been discovered that they would have to pay an extra charge of £6000, and it was not improbable that the corporation of Liverpool would eventually provide an asylum for that city, in which case the asylums board would find that it had too much instead of too little room.

Liverpool and Small-pox.

At the weekly meeting of the Health Committee held on May 22nd, the medical officer of health reported that the death-rate for the past week was 39 per 1000 of the population, as against 20 1 per 1000 in the previous year. In the hospitals there were now only 19 cases of small-pox. There were 432 cases of scarlet fever, 47 cases of typhoid fever, and 53 cases of diphtheria. During the week only one case of small-pox had been reported and that case referred to a woman who had arrived from London. However, on the day following that of the meeting of the Health Committee a fresh case was reported to the medical officer, that of a dock-gate man employed at one of the North-end docks. He was promptly removed to hospital and measures were at once taken to prevent the disease spreading.

May 27th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Bridgend Workhouse.

It is now some years since the attention of the Bridgend Board of Guardians was first directed to the inadequate accommodation at the workhouse and to the necessity for extensive alterations. As long ago as 1895 the medical officer to the workhouse (Mr. Wyndham Randall) made certain recommendations and advised specific structural additions, and he has from time to time repeated the advice which he then gave. Upon every favourable opportunity, too, the Poor-law inspector for Wales and Monmouthshire (Mr. F. T. Bircham) has pressed the matter upon the board of guardians as one of great urgency. The extensions required are estimated to cost about £13,000, and as the rateable value is high and is rapidly increasing, for within the area of the union there are extensive collieries, the expenditure of this sum would only involve an increased rate equal to ½*d.* in the £ for 30 years. In spite of this comparatively small sum the majority of the members of the Bridgend Board of Guardians have persistently refused to carry out the recommendations of their medical officer and to follow the advice of the Local Government Board inspector. A year ago when a definite motion upon the matter was before the board it was decided by 37 votes to seven to postpone the consideration of the question for a year. Subsequently a committee was appointed to report as to what were the most urgent alterations and additions required and this committee recommended the building of a kitchen and a laundry at a cost of £3500. The Local Government Board, however, refused to sanction the borrowing of this sum except on condition that the erection of an infirmary should be proceeded with, but the guardians declined to accept this condition. At a meeting of the board of guardians held on May 17th Mr. Bircham again referred to the subject and said that upon a recent visit to the workhouse he found in the sick wards 31 beds and 38 patients and that the wards swarmed with bugs. He also stated that there were no women's receiving ward, no proper lying-in ward, and no proper vagrant wards. At this same meeting Mr. Wyndham Randall presented a report from which it appears that the one nurse employed has sometimes had as many as 50 or 60 patients under her care, several of the cases being those of extremely severe and often fatal illnesses necessitating continuous watchful observation and long and careful attendance. Mr. Randall recommends the construction of a properly equipped hospital to contain at least 60 beds with accommodation for eight nurses, a lying-in ward, a convalescent room, detached wards for infectious and venereal cases, a separate ward for imbeciles with a paid attendant, and a cheerful day-room and dormitory for the children, with a paid nurse to look after them. It has been argued by some of the guardians that these extensions are unnecessary because in the future old age pensions will probably reduce the number of inmates in the workhouses, but, as Mr. Randall very properly points out in his report, there will still be a large amount of illness and of injuries with which the proposed hospital would have to deal, and with the rapid increase in the population of the district there has been, as might be expected, a corresponding increase in the number of sick persons treated in the workhouse, where only 14 deaths occurred in 1894, while there were 41 in 1901. It is difficult to believe that the conditions described, which are little short of a scandal, can be allowed to continue, and if the Local Government Board does not possess the power to alter them it is high time that such power was conceded.

The Wiltshire Medical Officer of Health.

There was a great deal of acrimony displayed at the meetings of the Wiltshire County Council three years ago when the question of appointing a medical officer of health for the county was discussed, but even those who opposed the appointment must by this time have become convinced of its necessity, for at the quarterly meeting of the council held on May 20th the salary of Mr. J. Tubb-Thomas (the medical officer of health) was increased from £500 to £600 per annum and it was decided to provide him with a clerk.

British Dental Association.

At the annual meeting of the British Dental Association, which was held at Shrewsbury on May 22nd, Mr. W. E. Harding, in his presidential address, said that the association had for many years been pressing on the Government the importance of attention to the teeth of our soldiers and sailors, and the breakdown of so many men in South Africa through preventable disease of the teeth at length induced the War Office to send out some dentists but the number was far too few to cope with the immense amount of work required. Mr. Harding also deplored the neglect to which the teeth of children attending public elementary schools are subjected and expressed the opinion that a question of such national importance ought to be dealt with by the State.

The New Factory Act and Sanitary Inspectors.

The Swansea Corporation has appointed an additional sanitary inspector whose duties will be specially connected with factories and workshops.—The Health Committee of the Rhondda Urban District Council has recommended the appointment of two additional sanitary inspectors, one of whom will be concerned with factories and workshops. Even with this additional staff there will be only seven inspectors for a population of 120,000 persons in this densely populated colliery district, although for years the Local Government Board has urged the desirability of adding to the number and in 1900 went so far as to refuse to sanction the appointment of one inspector, thus entailing on the district the loss of one half of his salary. The following year, although the conditions were unaltered, not only was sanction given to the re-appointment of the same inspector, but the Board's refusal of the previous year was withdrawn.

A Rate-supported General Hospital.

The Barry Urban District Council has already obtained the sanction of the Local Government Board to the expenditure from the rates of £14,000 upon the erection of a general hospital and the project has only been delayed on account of what it is hoped is only a temporary check in the growth of the town and therefore of its resources. It was thought, however, that in the present year an effort might be made to proceed with the building to commemorate the coronation and a plebiscite has been taken which has resulted in 1135 votes being given in favour of the scheme and 876 against it. The district council has decided, however, in view of the small majority not to build the hospital for the present but to clear off a debt, amounting to £1000, of the nursing institution, in favour of which 1560 votes were cast and only 412 against.

Vaccination Expenditure.

At the meeting of the Bodmin (Cornwall) Board of Guardians held on April 28th it was reported that the fees paid to the public vaccinators for the past three months amounted to £80, being £50 more than for the corresponding quarter of 1901. The chairman commented on the number of persons in good positions who were revaccinated by the public vaccinators and it was suggested that a list of such persons should be made and scrutinised by the guardians in the same way as those cases receiving out-door relief.—The Honiton (Devon) Board of Guardians at its meeting held on April 26th reported that the vaccination fees for the past quarter amounted to £104 more than for the corresponding quarter of 1901 and the opinion was expressed that the law should be amended in so far as it allowed persons to be revaccinated at their own houses at a considerable extra expense to the ratepayers.—At the meeting of the Totnes (Devon) Board of Guardians held on May 17th it was reported that the cost of vaccination for the past quarter amounted to £285, against £57 in the corresponding three months of 1901.—At the meeting of the Cardiff Board of Guardians held on May 17th attention was called to the increase in the amount paid for vaccination. In 1896 the sum was £796, whereas in 1901 it had increased to £1858. One of the guardians suggested that one public vaccinator should be appointed at a fixed salary, but the clerk remarked that even if the Local Government Board sanctioned such an appointment the fees would be the same as at present.

The Walter Collection of Antiquities.

Taunton Castle is now used as a museum by the Somersetshire Archæological Society and on May 21st the Lord Lieutenant of Somerset (the Earl of Cork and Orrery) formally opened the great hall of the castle, in which extensive restorations have been made. Lord Cork also presided at the formal throwing open of the fine collection of archæological remains of the stone, the bronze, the early British, and other periods presented to the society by Mr. Walter Winter Walter, M.R.C.S. Eng., L.S.A., of Stoke-sub-Hambden, Somerset, and in the course of his speech he remarked that through the liberality of Mr. Walter they had the most valuable and best local museum in Great Britain. Mr. E. J. Stanley, M.P., proposed a vote of thanks to Mr. Walter for his munificent gift, which was seconded by the Rev. Prebendary Askwith and carried unanimously. Mr. Richard Hensleigh Walter, M.B., C.M. Edin., suitably responded for his father.

May 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

A MEETING will be held at the Royal College of Surgeons in Ireland on June 2nd to elect a President, a vice-president, a council, and a secretary of the College for the ensuing year. The voting paper has been issued and it shows that Mr. Lambert Hepenstal Ormsby is the only candidate for the presidency. For the vice-presidency there are two applicants, Mr. Arthur Chance of the Mater Misericordiæ Hospital and Mr. John J. Cranny of Jervis-street Hospital. For the office of secretary there is only one candidate, Sir Charles A. Cameron, C.B. For the council eight Fellows have come forward for the vacancies caused by the retirement for various reasons of six members of the council of last year. The new candidates, in the order of their Fellowship seniority, as their names appear on the voting paper, are as follows:—Mr. John D. Hillis, Mr. Thomas Donnelly, Mr. Newell F. T. Porter, Mr. Joseph D. McFeely, Mr. Alexander J. McA. Blaney, Mr. William Taylor, Mr. Henry W. Oulton, and Mr. Thomas O'Connell Redmond. The election of examiners for the next year has recently taken place with the result that most of those who were examiners during last year have retained their places. In the subject of surgery, however, the choice of examiners has been postponed and it is understood that instead of two as at present four examiners will be appointed for the coming year. There are many applicants for the positions and some of the vacancies in the council are caused by the resignation of members who would prefer to be examiners in surgery.

D.S.O. for an Irish Army Medical Officer.

Lieutenant Williams, B.A. T.C.D., of the Indian Medical Service was last April at Singapore presented with the riband and cross of the "Distinguished Service Order" for his services with the China Expeditionary Force. He is a graduate of Dublin University and was well known in Dublin as a prominent member of the "Wanderers" football club.

Otological Society of the United Kingdom.

By permission of the Rev. the Provost a meeting of the Otological Society of the United Kingdom will take place in the Anatomical Department of the Medical School of Trinity College on May 31st. The agenda include papers by Professor D. J. Cunningham, Professor Coffey, Professor A. Birmingham, and Dr. Dempsey, all of Dublin.

Prevention of Consumption.

The annual meeting of the Ulster branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis was held in Belfast on May 20th. Dr. James Niven of Manchester, who was announced to speak, was not able to be present, but he sent a written statement as to the means used in Manchester to combat tuberculosis, and his assistant, Dr. James Beattie, delivered an address. Belfast needs to be thoroughly aroused on this question and it is all the more urgent considering the fact that the North of Ireland occupies a deplorable position with regard to the disease, the death-rate from consumption being half as much again per 1000 as that of Lancashire where the population is so much more dense, and it is four times as great as that of the best English county.

County Antrim Infirmary, Lisburn.

A three-days' bazaar in aid of the funds of the County Antrim Infirmary was opened on May 22nd and was in every respect a great success. In 1887, in honour of the first Jubilee of the late Queen Victoria, the town and neighbourhood of Lisburn presented an ambulance and in remembrance of the Diamond Jubilee the town of Lisburn purchased the adjoining house which was formed into nurses' quarters and private wards. The object of the bazaar was to raise £1000 to make necessary changes in the infirmary so as to bring it more up to date.

Death of Mr. William Thomson, M.D. R.U.I., J.P.

Dr. Thomson died on May 21st from acute pneumonia at his residence, Annahilt House, Hillsborough, co. Down. Educated at Queen's College, Belfast, Dr. Thomson graduated as M.D. of the Queen's University in 1864. Starting practice in Lisburn he was afterwards selected as medical officer of Annahilt Dispensary District, and as late as May 20th a locum-tenent was appointed to act in his place during the illness which has unhappily ended in his death. Dr. Thomson, who was a magistrate for the county of Down, was greatly respected by his friends and patients. He has left a widow and a young family.

Armagh Sewerage Scheme.

The Armagh Urban Council proposes to borrow £5000 to carry out a sewerage scheme and new disposal works, but before agreeing to the loan the Local Government Board has decided that an inquiry must be held by its inspector.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Glycosuria of Muscular Origin.

AT the meeting of the Academy of Sciences held on April 28th M. Cadéac and M. Maignon reported that they had observed in guinea-pigs and dogs that the ligature of a paw or the extensive crushing of muscles always had the effect of causing the appearance of glycuronic compounds in the urine, either alone or associated with glucose, and they were thereupon induced to extend their observations to the human subject. They were thus led to the discovery that every complete fracture of the limbs was followed, both in the infant and in the adult, by the elimination of glycuronic compounds (and sometimes also of glucose) commencing in general two or three days after the accident and continuing for three weeks or a month until the lesions associated with the fracture were entirely recovered from. Glycosuria, however, was not constant and when it occurred it was always preceded by the glycuronic products; it was always proportionate to the seriousness of the lesions and was therefore especially abundant in cases of multiple fracture. The saccharine principles thus excreted were evidently derived from the muscular system, for when an animal was killed after one of its feet had been crushed only traces of sugar were found in the healthy muscles, whereas the injured muscles contained considerable quantities of sugar.

An Interrupted Competition.

The competitions for the appointment of hospital surgeon (*chirurgien des hôpitaux*) have frequently been the occasion of scandals on a small scale and an unfortunate incident has once more drawn public attention to them. The competition, which is in progress at the present time and the examinations for which commenced a month ago, has just been suddenly interrupted by the resignation of the jury in a body. As always happens in these competitions, no sooner had the drawing of lots made known the names of the jurors than the competitors were able, on the principle of the *esprit de corps* of the various schools, to forecast who would be successful. But complications were not slow to arise among the jury, for one of the jurors saw with regret that two of his pupils who were competing were doomed to fail and then the incident occurred. Operative surgery on the dead body was the subject of examination and the operation required by the jury was "ligature of the femoral at the ring" (*ligature de la fémorale à l'anneau*). The question was ambiguous, for some of the candidates understood that the artery was to be ligatured at the femoral ring (*anneau crural*), while others understood that it was to be ligatured at the ring in the third adductor muscle of the thigh (adductor magnus), otherwise described as at its escape from Hunter's canal. Among the former were especially the candidates who had already been entrusted with the teaching of operative surgery at the Faculty of Medicine, where the expression "*ligature à l'anneau*" habitually signifies ligature at the femoral ring. The other candidates recollected that in the previous year the question had been expressly set as ligature at the femoral ring, and thinking that the intention of the examiners would be to avoid setting the same question at two competitions in succession, they performed ligature of the vessel at the other ring. One of the candidates even turned to the jury and asked "Which ring?" but no reply was given. Two of the candidates in their agitation opened the artery while searching for it. After the operation there was an animated discussion among the members of the jury, for some of them perceiving after all that the question was not plain, wished that portion of the examination to be cancelled, whilst others—namely, those whose *protégés* had guessed correctly—wished it to stand good. In the result the jury being divided into two equal parts decided on resigning—a course of action which would cancel the whole competition and require everything to be begun over again with another jury. The news caused a great scandal in the medical world and the incident was freely commented on even by the non-medical press. M. Mourier, director-general of the Assistance Publique, then assembled the jurors in his office and declined to accept their resignation. The competition therefore continues and is in progress at the present moment, but the chances of success of the various competitors are now very different from what they were before these singular proceedings.

Obituary.

Dr. Polaillon, honorary surgeon-in-chief of the Hôtel Dieu and member of the Academy of Medicine, died on May 24th. Dr. Beaudron, who held a hospital appointment as obstetric physician, died on May 23rd, aged 38 years.

May 27th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Influence of Diet on the Secretion of Hydrochloric Acid in the Stomach.

AT the last meeting of the Medical Society of Zürich Professor Cloetta read a paper on an Experimental Investigation as to the Influence of Diet on the Secretion of Hydrochloric Acid. Selecting four healthy puppy dogs he fed two of them exclusively on milk diet (adding the necessary iron salt) and the other two only on meat diet, of which they had 500 grammes (18 ounces) per diem. All of them grew equally well. After three months lavage of the stomach was performed; the stomachs of the dogs fed on milk were found to contain no hydrochloric acid whatever, but the stomachs of the dogs fed on meat diet contained 0·1 per cent. free hydrochloric acid. Three months later an examination gave the same result but the free hydrochloric acid had in the second case increased to 0·25 per cent. The animals were killed and the mucous membranes were immediately prepared for minute and detailed microscopic examination. No difference whatever could be detected in the microscopic structure. Professor Cloetta suggests that the secretion of hydrochloric acid deserves further investigation and that the nervous system plays an important part in cases of hyperchlorhydria.

Fracture of the Carpal Scaphoid Bone.

Dr. C. Kaufmann of Zürich has published an interesting *résumé* on cases of isolated fracture of the scaphoid bone. His assistant, Dr. Höfliger, published seven such cases last year, Dr. Baer and Dr. Ziegler have reported one each, and Dr. Kaufmann can now add four more, thus making a total of 13. It is very desirable that the surgical out-patient departments of hospitals should pay due attention to cases of so-called distortion of the hand and have skiagrams made of those where a fracture was possible or probable; they doubtlessly occur fairly frequently and it would be of great interest to examine the cases immediately after the fracture occurred. Dr. Kaufmann's most recent case had taken place four weeks previously to his seeing the patient and being able to make the diagnosis. In severe cases the symptoms consisted of stiffness of the joint, radial abduction of the hand, and pain and thickening, or even crepitus, over the scaphoid bone. In some cases, especially those of simple transverse fracture, the bone heals well and the only remaining symptom for months afterwards is pain on movement. A fall on the hand stretched forward produces typical fracture of the radius and a fall on the hand stretched backwards may produce isolated fracture of the scaphoid bone. The prognosis is good. The transverse fracture heals without treatment. Massage and active and passive movements promote recovery. Displacement of fragments or pseudarthrosis may prolong or impede recovery. In the latter case operative interference becomes necessary. Dr. Kaufmann now performs resection of the distal portion of the fractured bone after a dorsal incision in the so-called "tabatière"—i.e., the recess lying between the extensor tendons of the thumb In legal cases coming under the Workmen's Act, the working power of a man whose scaphoid bone has been fractured is diminished by one-third in the first year, one-fourth in the second, and one-sixth to one-tenth in the third year, progressive improvement being the rule. Thus, one or one and a half years' wages form an adequate remuneration for insured workmen suffering from this fracture.

Zürich, May 24th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Samaritan Free Hospital for Women, Montreal.

THE annual meeting of the Board of Managers of the Montreal Samaritan Free Hospital for Women was held recently in that city and according to the reports presented there were treated in that institution during the past hospital year 133 patients, an increase of 20 compared with the previous year. In the outdoor department of the hospital over 200 received free advice and treatment. Among the total number treated there were five deaths, a decrease in comparison with the previous year. The treasurer's report showed an encouraging condition of the finances. Commencing with a balance to the good at the beginning of the year of $455·52, the receipts totalled $3733·74 and the expenses $3149·75.

A Montreal Physician Honoured.

At the recent meeting of the Association of American Physicians, held at Philadelphia, U.S.A., Dr. James Stewart, Professor of Medicine and of Clinical Medicine in McGill University, Montreal, was elected to the presidency of that prominent American organisation. Dr. Stewart is a graduate of McGill University. From 1883 to 1891 he was Professor of Materia Medica and since that time he has held the chair of Medicine. He is a member of the Board of Trustees of the National Sanitarium Association.

Canadian Physicians receiving British Appointments.

Dr. J. M. Jory, St. Catherine's, Ontario, and Dr. D. M. Anderson, house surgeon to the Toronto General Hospital, have been appointed surgeons to the fourth Canadian contingent for South Africa. Dr. Harry W. Spence, formerly house surgeon to the Toronto General Hospital, has been appointed by the British Government medical officer of one of the concentration camps in Natal, South Africa. Dr. H. A. Beatty, M.R.C.S. Eng., of Toronto, has lately received a cablegram offering him the surgical registrarship of the Westminster Hospital in London. Dr. Beatty has recently returned to Toronto after spending four years in post-graduate study abroad and he was lately senior house surgeon at Westminster Hospital. Dr. Beatty is a graduate of Toronto University.

Canadian Association for the Prevention of Tuberculosis.

The annual meeting of the above association was held in Ottawa in the latter part of April under the presidency of Sir James Grant. Prominent medical men were present from all the provinces of the Dominion. Dr. S. A. Knopf of New York delivered an address on the Mission of the Societies *for the Prevention of Consumption in the Anti-Tuberculosis* Crusade. It was decided to centralise the organisation at the capital and to have a permanent paid secretary. One important outcome of the conference has just been announced. Sir William Macdonald (Montreal) and Mr. W. C. Edwards, M.P. (Ottawa), have offered to erect at their own expense sanatoriums for consumptives near their respective cities. The following were the officers elected for the ensuing year: President, Mr. W. C. Edwards, M.P.; secretary, Dr. H. B Small (Ottawa).

Canada and Diseased Immigrants.

There has recently been advanced a great deal of objection to the Canadian Government permitting diseased immigrants to find homes in Canada. As a result of the agitation the Government has now before the House of Commons a Bill proposing to amend the Immigration Act and conferring power on the Governor in Council to prohibit by proclamation or order the landing in Canada of persons suffering from dangerous or infectious diseases, having special regard to trachoma and favus. Permission will be given to them to land for medical treatment only and for a period that may be *determined by the order or proclamation. This action of* the Government has been brought about through the appointment last September by the United States Immigration Department at Washington of a special examining board at the port of Montreal which passes judgment upon all candidates destined for places in the United States. A good many of these immigrants have been rejected by this board and have found homes for themselves in Canada.

Deaths from Tuberculosis in Ontario in 1900.

According to the report of the Registrar-General of Ontario which has only recently been given to the medical profession this disease has maintained its pre-eminence during 1900, having caused no less than 3484 deaths. The excess in cities is notable, there having been recorded 1081 deaths in a population of 475,222. The rate per 1000 for cities is 2·27, as compared with 1·59 for the entire province, or 1·4 for the rest of the province outside the cities. In Ontario the deaths of all infants under four months when no specific cause other than atrophy, malnutrition, marasmus, or scrofula was given have been entered under tuberculosis, and in this way the rate is high and probably relatively higher than in other countries which do not place deaths from these conditions under tuberculosis.

Deaths from Cancer in Ontario in 1900.

The total deaths recorded as due to this disease in the Province of Ontario in 1900 were 1055 as compared with 1041 and 975 for the two preceding years. The following figures show that cancer has increased by 100 per cent. in the past decade. In 1891 the deaths reported were 579; in 1892, 676; in 1893, 678, in 1894, 621; in 1895, 620; in 1896, 731; in 1897, 927; in 1898, 975; in 1899, 1041; and in 1900, 1055. The exact ratio of deaths from cancer to the total deaths was one to 37 in 1891 and one to 28 in 1900. Out of the 1055 deaths in 1900 from this cause 329 occurred in the 14 cities of the Province.

Toronto, May 5th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Three Important Congresses.

THREE important congresses are to be held in the United States under the plans proposed by the Pan-American Conference held in Mexico last winter, to carry into effect long-needed coöperation between all the Governments in the Western Hemisphere in sanitary and customs regulations, and to consider the coffee crisis. The first, the Sanitary Congress, will meet in Washington on Oct. 1st, and the other two in New York City, the Customs Congress on Oct. 15th, and the Coffee Congress on Nov. 1st. The programme for the first congress, to which all the republics have arranged to send technical delegates, is now being prepared by Surgeon-General Wyman of the Marine Hospital Service. It is proposed to establish an "International Sanitary Bureau" of experts to sit permanently in Washington to protect the public health of the republics and thereby to facilitate their commercial relations at all seasons. The bureau is to consider and to decide on all measures intended to prevent the spread of contagious diseases between the republics, or their invasion from outside, by the establishment and maintenance of a uniform system of international inspection, disinfection, and detention for persons or merchandise coming from abroad by land or sea, by means of sanitary stations in the ports of each country which shall be entirely under the control of the respective Governments. It is proposed that prohibitive quarantine shall be discontinued in regard to manufactured articles and all other merchandise; that merchandise proceeding from *non-infected ports and places* but coming through infected districts without stopping longer than the transit itself requires shall not be subject to detention or to any other sanitary precaution except the indispensable inspection at the point of destination, and that this inspection and the delay that it requires shall in no case exceed the time absolutely necessary to carry it out properly. These rules are to be made applicable to merchandise coming by rail but they are not to be enforced in regard to cattle, raw hides, rags, and the effects belonging to immigrants, which are to be dealt with as before. The Customs Congress at New York will be composed of delegates appointed by each Government from among its chief customs officers, consuls, presidents or members of its chambers of commerce, and prominent merchants or other persons known to possess technical or special knowledge in customs matters. Among the matters which the congress is to consider are uniformity of regulations for the entry, despatch, and clearance of the vessels engaged in international commerce, uniformity and simplicity of customs, formalities relating to the manifests of vessels and to the wording and form of consular invoices and custom-house declarations, and formalities for the clearance of merchandise and baggage. Adequate means are also to be considered for establishing a common nomenclature of the products and merchandise of the American republics in English, Spanish, Portuguese, and French, in order that it may serve as a basis for the statistical data of imports and exports in accordance with a uniform system and without interfering with the regulations which each country may have adopted for the compilation of its own statistics, and in order that it may be adopted with greater detail and specification in the tariff schedules and in the other customs laws of the said countries and that it may serve as a basis for the collection of the dues that each republic may have established. Also for the organisation of a permanent Customs Commission composed of individuals possessing technical and special knowledge which, as a branch of the International Bureau of the American republics or in any other form that the congress may think proper, shall be charged particularly with the execution of the customs and tariff laws of the nations of America for the purpose of suggesting to the respective Governments the enactment of laws and regulations which, in so far as they relate to custom-house formalities, shall tend to facilitate mercantile traffic.

Reciprocity in Medical Licensure.

During the month of January last there was held in the city of Chicago a meeting of representatives of the examining boards of Illinois, Wisconsin, Indiana, and Michigan, at which was appointed a committee to formulate a policy and continuing for three weeks or a month until the lesions associated with the fracture were entirely recovered from. Glycosuria, however, was not constant and when it occurred it was always preceded by the glycuronic products; it was always proportionate to the seriousness of the lesions and was therefore especially abundant in cases of multiple fracture. The saccharine principles thus excreted were evidently derived from the muscular system, for when an animal was killed after one of its feet had been crushed only traces of sugar were found in the healthy muscles, whereas the injured muscles contained considerable quantities of sugar.

An Interrupted Competition.

The competitions for the appointment of hospital surgeon (*chirurgien des hôpitaux*) have frequently been the occasion of scandals on a small scale and an unfortunate incident has once more drawn public attention to them. The competition, which is in progress at the present time and the examinations for which commenced a month ago, has just been suddenly interrupted by the resignation of the jury in a body. As always happens in these competitions, no sooner had the drawing of lots made known the names of the jurors than the competitors were able, on the principle of the *esprit de corps* of the various schools, to forecast who would be successful. But complications were not slow to arise among the jury, for one of the jurors saw with regret that two of his pupils who were competing were doomed to fail and then the incident occurred. Operative surgery on the dead body was the subject of examination and the operation required by the jury was "ligature of the femoral at the ring" (*ligature de la fémorale à l'anneau*). The question was ambiguous, for some of the candidates understood that the artery was to be ligatured at the femoral ring (*anneau crural*), while others understood that it was to be ligatured at the ring in the third adductor muscle of the thigh (adductor magnus), otherwise described as at its escape from Hunter's canal. Among the former were especially the candidates who had already been entrusted with the teaching of operative surgery at the Faculty of Medicine, where the expression "*ligature à l'anneau*" habitually signifies ligature at the femoral ring. The other candidates recollected that in the previous year the question had been expressly set as ligature at the femoral ring, and thinking that the intention of the examiners would be to avoid setting the same question at two competitions in succession, they performed ligature of the vessel at the other ring. One of the candidates even turned to the jury and asked "Which ring?" but no reply was given. Two of the candidates in their agitation opened the artery while searching for it. After the operation there was an animated discussion among the members of the jury, for some of them perceiving after all that the question was not plain, wished that portion of the examination to be cancelled, whilst others—namely, those whose *protégés* had guessed correctly—wished it to stand good. In the result the jury being divided into two equal parts decided on resigning—a course of action which would cancel the whole competition and require everything to be begun over again with another jury. The news caused a great scandal in the medical world and the incident was freely commented on even by the non-medical press. M. Mourier, director-general of the Assistance Publique, then assembled the jurors in his office and declined to accept their resignation. The competition therefore continues and is in progress at the present moment, but the chances of success of the various competitors are now very different from what they were before these singular proceedings.

Obituary.

Dr. Polaillon, honorary surgeon-in-chief of the Hôtel Dieu and member of the Academy of Medicine, died on May 24th. Dr. Beaudron, who held a hospital appointment as obstetric physician, died on May 23rd, aged 38 years.

May 27th.

The Influence of Diet on the Secretion of Hydrochloric Acid in the Stomach.

AT the last meeting of the Medical Society of Zürich Professor Cloetta read a paper on an Experimental Investigation as to the Influence of Diet on the Secretion of Hydrochloric Acid. Selecting four healthy puppy dogs he fed two of them exclusively on milk diet (adding the necessary iron salt) and the other two only on meat diet, of which they had 500 grammes (18 ounces) per diem. All of them grew equally well. After three months lavage of the stomach was performed; the stomachs of the dogs fed on milk were found to contain no hydrochloric acid whatever, but the stomachs of the dogs fed on meat diet contained 0·1 per cent. free hydrochloric acid. Three months later an examination gave the same result but the free hydrochloric acid had in the second case increased to 0·25 per cent. The animals were killed and the mucous membranes were immediately prepared for minute and detailed microscopic examination. No difference whatever could be detected in the microscopic structure. Professor Cloetta suggests that the secretion of hydrochloric acid deserves further investigation and that the nervous system plays an important part in cases of hyperchlorhydria.

Fracture of the Carpal Scaphoid Bone.

Dr. C. Kaufmann of Zürich has published an interesting *résumé* on cases of isolated fracture of the scaphoid bone. His assistant, Dr. Höfliger, published seven such cases last year, Dr. Baer and Dr. Ziegler have reported one each, and Dr. Kaufmann can now add four more, thus making a total of 13. It is very desirable that the surgical out-patient departments of hospitals should pay due attention to cases of so-called distortion of the hand and have skiagrams made of those where a fracture was possible or probable; they doubtlessly occur fairly frequently and it would be of great interest to examine the cases immediately after the fracture occurred. Dr. Kaufmann's most recent case had taken place four weeks previously to his seeing the patient and being able to make the diagnosis. In severe cases the symptoms consisted of stiffness of the joint, radial abduction of the hand, and pain and thickening, or even crepitus, over the scaphoid bone. In some cases, especially those of simple transverse fracture, the bone heals well and the only remaining symptom for months afterwards is pain on movement. A fall on the hand stretched forward produces typical fracture of the radius and a fall on the hand stretched backwards may produce isolated fracture of the scaphoid bone. The prognosis is good. The transverse fracture heals without treatment. Massage and active and passive movements promote recovery. Displacement of fragments or pseudarthrosis may prolong or impede recovery. In the latter case operative interference becomes necessary. Dr. Kaufmann now performs resection of the distal portion of the fractured bone after a dorsal incision in the so-called "tabatière"—i.e., the recess lying between the extensor tendons of the thumb. In legal cases coming under the Workmen's Act, the working power of a man whose scaphoid bone has been fractured is diminished by one-third in the first year, one-fourth in the second, and one-sixth to one-tenth in the third year, progressive improvement being the rule. Thus, one or one and a half years' wages form an adequate remuneration for insured workmen suffering from this fracture.

Samaritan Free Hospital for Women, Montreal.

THE annual meeting of the Board of Managers of the Montreal Samaritan Free Hospital for Women was held recently in that city and according to the reports presented there were treated in that institution during the past hospital year 133 patients, an increase of 20 compared with the previous year. In the outdoor department of the hospital over 200 received free advice and treatment. Among the total number treated there were five deaths, a decrease in comparison with the previous year. The treasurer's report showed an encouraging condition of the finances. Commencing with a balance to the good at the beginning of the year of $455·52, the receipts totalled $3733·74 and the expenses $3149·75.

A Montreal Physician Honoured.

At the recent meeting of the Association of American Physicians, held at Philadelphia, U.S.A., Dr. James Stewart, Professor of Medicine and of Clinical Medicine in McGill University, Montreal, was elected to the presidency of that prominent American organisation. Dr. Stewart is a graduate of McGill University. From 1883 to 1891 he was Professor of Materia Medica and since that time he has held the chair of Medicine. He is a member of the Board of Trustees of the National Sanitarium Association.

Canadian Physicians receiving British Appointments.

Dr. J. M. Jory, St. Catherine's, Ontario, and Dr. D. M. Anderson, house surgeon to the Toronto General Hospital, have been appointed surgeons to the fourth Canadian contingent for South Africa. Dr. Harry W. Spence, formerly house surgeon to the Toronto General Hospital, has been appointed by the British Government medical officer of one of the concentration camps in Natal, South Africa. Dr. H. A. Beatty, M.R.C.S. Eng., of Toronto, has lately received a cablegram offering him the surgical registrarship of the Westminster Hospital in London. Dr. Beatty has recently returned to Toronto after spending four years in post-graduate study abroad and he was lately senior house surgeon at Westminster Hospital. Dr. Beatty is a graduate of Toronto University.

Canadian Association for the Prevention of Tuberculosis.

The annual meeting of the above association was held in Ottawa in the latter part of April under the presidency of Sir James Grant. Prominent medical men were present from all the provinces of the Dominion. Dr. S. A. Knopf of New York delivered an address on the Mission of the Societies for the Prevention of Consumption in the Anti-Tuberculosis Crusade. It was decided to centralise the organisation at the capital and to have a permanent paid secretary. One important outcome of the conference has just been announced. Sir William Macdonald (Montreal) and Mr. W. C. Edwards, M.P. (Ottawa), have offered to erect at their own expense sanatoriums for consumptives near their respective cities. The following were the officers elected for the ensuing year: President, Mr. W. C. Edwards, M.P.; secretary, Dr. H. B. Small (Ottawa).

Canada and Diseased Immigrants.

There has recently been advanced a great deal of objection to the Canadian Government permitting diseased immigrants to find homes in Canada. As a result of the agitation the Government has now before the House of Commons a Bill proposing to amend the Immigration Act and conferring power on the Governor in Council to prohibit by proclamation or order the landing in Canada of persons suffering from dangerous or infectious diseases, having special regard to trachoma and favus. Permission will be given to them to land for medical treatment only and for a period that may be determined by the order or proclamation. This action of the Government has been brought about through the appointment last September by the United States Immigration Department at Washington of a special examining board at the port of Montreal which passes judgment upon all candidates destined for places in the United States. A good many of these immigrants have been rejected by this board and have found homes for themselves in Canada.

Deaths from Tuberculosis in Ontario in 1900.

According to the report of the Registrar-General of Ontario which has only recently been given to the medical profession this disease has maintained its pre-eminence during 1900, having caused no less than 3484 deaths. The excess in cities is notable, there having been recorded 1081 deaths in a population of 475,222. The rate per 1000 for cities is 2·27, as compared with 1·69 for the entire province, or 1·4 for the rest of the province outside the cities. In Ontario the deaths of all infants under four months when no specific cause other than atrophy, malnutrition, marasmus, or scrofula was given have been entered under tuberculosis, and in this way the rate is high and probably relatively higher than in other countries which do not place deaths from these conditions under tuberculosis.

Deaths from Cancer in Ontario in 1900.

The total deaths recorded as due to this disease in the Province of Ontario in 1900 were 1055 as compared with 1041 and 975 for the two preceding years. The following figures show that cancer has increased by 100 per cent. in the past decade. In 1891 the deaths reported were 579; in 1892, 676; in 1893, 678; in 1894, 621; in 1895, 620; in 1896, 731; in 1897, 927; in 1898, 975; in 1899, 1041; and in 1900, 1055. The exact ratio of deaths from cancer to the total deaths was one to 37 in 1891 and one to 28 in 1900. Out of the 1055 deaths in 1900 from this cause 329 occurred in the 14 cities of the Province.

Toronto, May 5th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Three Important Congresses.

THREE important congresses are to be held in the United States under the plans proposed by the Pan-American Conference held in Mexico last winter, to carry into effect long-needed coöperation between all the Governments in the Western Hemisphere in sanitary and customs regulations, and to consider the coffee crisis. The first, the Sanitary Congress, will meet in Washington on Oct. 1st, and the other two in New York City, the Customs Congress on Oct. 15th, and the Coffee Congress on Nov. 1st. The programme for the first congress, to which all the republics have arranged to send technical delegates, is now being prepared by Surgeon-General Wyman of the Marine Hospital Service. It is proposed to establish an "International Sanitary Bureau" of experts to sit permanently in Washington to protect the public health of the republics and thereby to facilitate their commercial relations at all seasons. The bureau is to consider and to decide on all measures intended to prevent the spread of contagious diseases between the republics, or their invasion from outside, by the establishment and maintenance of a uniform system of international inspection, disinfection, and detention for persons or merchandise coming from abroad by land or sea, by means of sanitary stations in the ports of each country which shall be entirely under the control of the respective Governments. It is proposed that prohibitive quarantine shall be discontinued in regard to manufactured articles and all other merchandise; that merchandise proceeding from non-infected ports and places but coming through infected districts without stopping longer than the transit itself requires shall not be subject to detention or to any other sanitary precaution except the indispensable inspection at the point of destination, and that this inspection and the delay that it requires shall in no case exceed the time absolutely necessary to carry it out properly. These rules are to be made applicable to merchandise coming by rail but they are not to be enforced in regard to cattle, raw hides, rags, and the effects belonging to immigrants, which are to be dealt with as before. The Customs Congress at New York will be composed of delegates appointed by each Government from among its chief customs officers, consuls, presidents or members of its chambers of commerce, and prominent merchants or other persons known to possess technical or special knowledge in customs matters. Among the matters which the congress is to consider are uniformity of regulations for the entry, despatch, and clearance of the vessels engaged in international commerce, uniformity and simplicity of customs, formalities relating to the manifests of vessels and to the wording and form of consular invoices and custom-house declarations, and formalities for the clearance of merchandise and baggage. Adequate means are also to be considered for establishing a common nomenclature of the products and merchandise of the American republics in English, Spanish, Portuguese, and French, in order that it may serve as a basis for the statistical data of imports and exports in accordance with a uniform system and without interfering with the regulations which each country may have adopted for the compilation of its own statistics, and in order that it may be adopted with greater detail and specification in the tariff schedules and in the other customs laws of the said countries and that it may serve as a basis for the collection of the dues that each republic may have established. Also for the organisation of a permanent Customs Commission composed of individuals possessing technical and special knowledge which, as a branch of the International Bureau of the American republics or in any other form that the congress may think proper, shall be charged particularly with the execution of the customs and tariff laws of the nations of America for the purpose of suggesting to the respective Governments the enactment of laws and regulations which, in so far as they relate to custom-house formalities, shall tend to facilitate mercantile traffic.

Reciprocity in Medical Licensure.

During the month of January last there was held in the city of Chicago a meeting of representatives of the examining boards of Illinois, Wisconsin, Indiana, and Michigan, at which was appointed a committee to formulate a policy for reciprocity in licensure between the several United States. The following propositions submitted by this committee at the meeting were adopted. First, that a licence or certificate of qualification of at least one year's date and based upon presentation of a satisfactory diploma and an examination before a board in specified branches of medicine and surgery may be accepted at the discretion of the board in lieu of an examination, and as a basis on which the licence of the State may be issued. Secondly, that a licence or certificate of qualification issued by a State board of registration or by medical examiners as to the reputability of the applicant may be accepted at the discretion of a board in lieu of an examination and as a basis upon which the licence of the State may be issued. Owing to the differences which exist in the laws of the several States with regard to medical licensure it was only possible for the confederation to recommend the policy upon which the reciprocal exchange of certificates must be arranged between the States reciprocating; also the standard of preliminary education as well as that of the medical qualifications of licentiates must be a matter of agreement between reciprocating States.

Proposed Union of the Medical Societies of the State of New York.

The Council of the State Medical Association and the State Medical Society of New York State have appointed committees to confer on the question of a union of the medical profession of the State. No date has yet been set for the conference, which will undoubtedly mean much to the future of the State medical organisations. The Medical Society of the County of New York is but one of many such societies, all of which are parts of the Medical Society of the State of New York. This system of medical societies was created by Act of Legislature in 1806; in 1882 the State Medical Society abolished what is called the code of ethics by a substantial majority, thus allowing its members the privilege of meeting any legal practitioner of medicine in consultation. The American Medical Association, of which the State and county medical associations are parts, was organised as the result of a convention held in this city in 1846.

No Quarantine against Cuba.

For the first time in many years the port of New York is not quarantined against Cuban ports; this is the season when such quarantine has been rigidly enforced. But there is no yellow fever in Cuba and every effort is being made to keep the island entirely free from it this season. In fact, there is reason for quarantining Cuba against New York, there being danger of carrying small-pox from this port to the Cuban ports. This proves the great advance in sanitary matters secured in Cuba in the last few years.

May 19th.

DONATIONS AND BEQUESTS.—Under the will of Miss Harriet Gosling £300 are bequeathed to the Middlesex Hospital.—The late Mr. Benjamin Weir, for many years chairman of the Board of Works, has bequeathed the whole of his property under trust for the founding of a hospital for Balham and Streatham.

THE PUBLIC VACCINATOR AND THE PUBLIC.—The Holywell (Flintshire) Board of Guardians, at a recent meeting, made some allusions to persons who employed the public vaccinator when they could well afford to pay for the operation. The chief constable of Flintshire, in a letter addressed to the guardians, has since then stated that he pays towards free public vaccination, which is not simply pauper vaccination, and as he is a member of the public he contends that he and his family are entitled to be vaccinated at the cost of the rates to which he has for years paid and from which hitherto he has derived no personal benefit.—At a recent meeting of the Cardigan Board of Guardians a motion was passed to publish a list of well-to-do persons who had been vaccinated by the public vaccinator. The attention of the Local Government Board having been drawn by a local correspondent to the matter a reply was received stating that the Board was not aware of any legal authority under which the guardians could pay for such lists, and any person whose name was published in such list would have good ground for complaint against the guardians, as it was the intention of the Legislature that the benefits of vaccination should be open to all classes of the population, and the Board strongly deprecated any such action on the part of the Cardigan Guardians.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE seventy-fourth session of the General Council of Medical Education and Registration was opened on Tuesday last, May 27th, at the office of the Council, Sir William Turner, K.C.B., the President, being in the chair.

The *personnel* of the Council at this session is the same as it was at the special session in February last.

In a business-like introductory address Sir William Turner outlined the work that lay before the Council and obviously hoped that the session would be a brief one. And in view of the fact that a special session of the Council has already been held this year the Council no doubt desires, if possible, to complete its work by the end of this week.

It is clear that the Council intends to use to the full its powers to maintain a uniformly high standard of preliminary medical education. The examinations in chemistry, physics, and biology conducted by the various licensing bodies are to be systematically reported upon. As the President pointed out, physics and biology have been added to the medical curriculum since any official inquiry has been made as to the standard of the various licensing bodies with regard to the ancillary fundamental sciences, while no visitations of the examinations in chemistry have been made for 20 years, not, in fact, since the medical and surgical corporations in the United Kingdom were reported upon in 1881-82.

An interesting debate arose on Tuesday with regard to a communication received from the Council of the British Medical Association asking the General Medical Council to receive a deputation to consider the subject of the preliminary education of the medical profession. The communication took the form of a report from the Preliminary Education Committee of the Association and was referred to the Executive Committee of the Council. This body considered that the report of the Preliminary Education Committee of the British Medical Association ignored all the work hitherto done by the Council in this very direction and recommended that the deputation should not be received. Mr. Horsley protested against this and as a result of the debate it would seem that the committee of the Association had not intended their report to convey a slight upon the obvious energy of the present Council in the direction of improving preliminary education. We are glad that this feeling prevailed in the Council and that it has been decided that the deputation shall be received by the Education Committee of the General Medical Council.

On Wednesday the time of the Council was mainly occupied in the hearing of penal cases. The first and most important case, that of Dr. Marcus Robert Phipps Dorman, was considered *in camerâ* in the interests of persons other than the complainant and the accused. This procedure is, we believe, an innovation, but in the circumstances it was a wise one and one that may well be followed in similar cases should they unfortunately occur.

TUESDAY, MAY 27TH.

THE seventy-third half-yearly session of the General Council of Medical Education and Registration was opened to-day in the Hall of the Council, Oxford-street, London. The 31 members constituting the Council were all present. Sir WILLIAM TURNER, K.C.B., the President of the Council, occupied the chair.

The President's Address.

The PRESIDENT opened the proceedings with an address. He said:—

During the present session the reports of the inspector and visitors on the final examinations held by the University of Dublin, by the Conjoint Board of the three Medical and Surgical Corporations in Scotland, and by the Royal University of Ireland will be submitted to you. It is satisfactory to read that the visitor and inspector report in each case that the examination is "sufficient," and to observe that their criticisms refer to questions of detail. The scheme of inspection during the present year of the final examinations of the English Universities and the Irish Corporations has been arranged and members of Council have consented to act as visitors along with the inspector. Arrangements are also being made in accordance with the resolution of the Council (Minutes, Feb. 26th, 1902), for a visitation of the next examination in chemistry, physics, and biology of the Conjoint Examining Board of the Royal College of Physicians of London and the Royal College of Surgeons of England. By a further resolution the Council empowered your President and treasurers to arrange for a suitable remuneration to the gentlemen who are to act as visitors of this examination. It will be necessary to obtain the sanction of the Privy Council. The Council by its resolution of Feb. 26th has also intimated that it is desirable to have the examinations in chemistry, physics, and biology conducted by the licensing bodies generally, visited and reported on. Since physics and biology became a part of the medical curriculum no visitations of the examinations in the ancillary sciences have been made.

Since the special meeting of the Council in February the Bill for "the better training of midwives and to regulate their practice" has passed the second reading in the House of Commons and was referred to the Grand Committee on Law with certain additional members. Amendments prepared in consultation with the Midwives Bill Committee of the Council were moved by Sir John Batty Tuke, as also amendments by other members. The Bill, however, passed the Committee with but little change. The Grand Committee will report on the Bill on June 6th and it will probably be read a third time on June 13th. Owing to the pressure on the time of Parliament by the introduction of measures of more general scope and interest no progress has been made in Parliament with the Penal and Disciplinary Bill prepared by the Council some time ago and read for a first time during two sessions.

The Council will receive during the session reports from its own committees on various questions which have from time to time been referred to them. The Financial Relations Committee will make suggestions to provide for an increase in the income of the Council. Since a maximum registration fee of £5 was fixed by the Act of 1858 not only has the number of Members of Council been materially increased by the Direct Representatives elected by the profession and by additional members chosen by the Universities but the duties to be discharged by the Council have also multiplied. Although the value of the assets of the Council has materially increased through the rise in the value of its property in Oxford-street and Hanover-square its income has not improved and under present arrangements does not meet the expenditure. The Financial Relations Committee will therefore submit proposals for your consideration.

The Public Health Committee will again report on the question of the amount of outdoor or practical sanitary work to be done and on the distribution of the time to be given by candidates for a registrable diploma in public health.

The business of a penal and disciplinary character demanding the attention of the Council is more than usually heavy, but it is gratifying to find that no registered practitioner is to be charged with the offence of covering and no new case of a practitioner associating himself with medical aid societies which systematically canvass for patients will have to be considered.

An Indian edition of the Addendum to the British Pharmacopœia has been published, and the Government of India has purchased the greater part of the first issue of 4000 copies.

We have been requested by the Privy Council to send a delegate to an International Congress to be held in Brussels on the subject of a proposed International Pharmacopœia limited to drugs of a drastic nature. At the May session held in 1900 I was authorised to appoint one or more members to act as delegates and the chairman of the Pharmacopœia Committee has consented to represent the Council.

As a result of the extension of Part II. of the Medical Act (1886) to Italy a list of foreign practitioners appears for the first time in the Medical Register; the name and qualification of one practitioner are enrolled in the published volume and a second practitioner has subsequently been registered.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the Council thanked the President for his address.

Business Committee.

This committee was constituted as follows: Dr. MacAlister (chairman), Mr. Bryant, Dr. Bruce, and Sir Christopher Nixon.

Results of Examinations.

Mr. H. E. ALLEN, Registrar, presented to the Council the following documents:—

(a) Table showing results of professional medical examinations during 1901.

(b) Table showing results of professional examinations for qualifications in sanitary science, public health or State medicine during 1901.

(c) Table showing results of professional dental examinations during 1901.

(d) Table showing results of preliminary examinations during 1901.

(e) Answers sent by the medical authorities as to the exemptions granted by them in any part of their examinations during the year 1901.

(f) Table showing results of competition held on Feb. 3rd, 1902, for commissions in the medical staff of the Royal Navy.

(g) Table showing results of competition held in August 1901, for commissions in the Indian Medical Service.

The documents were formally received and entered on the minutes and on the motion of Dr. P. HERON WATSON, seconded by Sir CHRISTOPHER NIXON, it was agreed—

> That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy and to the Under-Secretary of State for India, respectively, for the returns which they have respectively again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council.

Mr. BROWN moved that the answers sent by the medical authorities as to the exemptions which they had granted should be referred to the Examination Committee.

Mr. JACKSON seconded this motion.

Mr. BALL called attention to a footnote to table (a) which he said savoured of what was called an Irish bull, though it lacked some of the essentials. This footnote said that "candidates who presented themselves in all the subjects but who omitted some are included in above." This referred to the examination of the Conjoint Board in Ireland and he was told by the registrar of that body that what it really meant was that candidates who were examined in some subjects and who passed or were rejected in those subjects were included in the list although they might not have covered the entire number of subjects which would justify their passing the whole examination. This raised an important question as to the value of these tables, because they contained lists of those who were rejected in parts of the examination and who passed in parts, so that it was quite possible that some candidates were returned as being rejected and as having passed at the same examination. There was another point, and that was the very large number of rejections apparently at the Conjoint Boards in Ireland and in Scotland. This was to a certain extent made up of men who were rejected over and over again and figured as a rejection each time they came up. In order to estimate properly the value of the figures in the table he thought it very desirable to know exactly what was the number of men who passed or failed to pass at their first trial and what the number of men who came up time after time for examination. Later he would move a resolution on the subject desiring this information from the various licensing bodies.

Mr. HORSLEY pointed out that the answers of the bodies made no reference to exemptions in the higher examinations and that in this respect they failed to meet the wishes of the Council.

The motion of Mr BROWN was then put from the chair and agreed to.

Appointment of Assistant Examiner.

On the motion of Sir HUGH BEEVOR it was agreed:—

> That Mr. Francis James Stewart, M.B., M.S., F.R.C.S., be appointed an assistant examiner in surgery to the Apothecaries' Society of London for a period of four years, vice Mr. L. A. Dunn who retires by rotation.

The Midwives Bill.

The next order on the paper was the following notice of motion by Mr BROWN:—

> That in the opinion of the Council the Midwives Bill, as amended by the House of Commons Grand Committee on Law, does not contain the

safeguards necessary to protect the public against the practice of midwifery by ignorant and incompetent persons.

Mr. BROWN asked leave to have consideration of this proposal deferred until the Council had received from the Midwives Bill Committee a report on the remit made to them as respects the Bill during the special session of the Council held last February. He formally moved to that effect.

Mr. JACKSON seconded and the motion was agreed to after a remark by Sir CHRISTOPHER NIXON that it was a little late in the day to take action on this matter at all.

Dental Business

The REGISTRAR (Mr. H. E. Allen) read the following report from the Executive Committee on the dental business transacted since the November session of the Council :—

The prescribed conditions in each case having been duly fulfilled the names of the undermentioned persons have been restored to the Dentists' Register, from which they had been erased in conformity with the provisions of Section 12 of the Dentists Act.—Francis G. Bridgman, William Brown, George P. Caldwell, Frank H. Carpenter, Samuel Earp, Henry J. A. Geercke, James Hitchcock, Percy B. Hutchinson, Francis Jones, George H. Jones, Francis Lloyd, James A. Milliken, John C. Oliver, Henry J. Parker, Charles E. Tucker, John W. Wheeler.—The treasurers laid before the committee the usual statements of accounts duly audited of the receipts and expenditure of the dental fund of the General Medical Council for the year ending Dec. 31st, 1901, and directed that the summary be laid before both Houses of Parliament.—The committee considered an application for the registration as an additional title of the degree of bachelor of dental surgery of the University of Birmingham, and referred the question to the Dental Education and Examination Committee, with a request that it should report thereon to the Council during the present session.

In moving that the foregoing report should be received and entered on the minutes Dr. MACALISTER mentioned that from an examination of the regulations proposed by Birmingham University the committee thought that the University's new degree would be one worthy of their recognition.

Financial Relations.

Consideration of this subject was put off till Friday in consequence of the report of the committee not being ready.

Prevention of Personation.

On the suggestion of Mr. HORSLEY it was resolved to consider on another day the remaining portion of the report of the Committee on Prevention of Personation, the comments of the Registrars on the proposals of the committee to be meanwhile printed and circulated.

The British Medical Association and the Preliminary Examination.

The REGISTRAR read the following report from the Executive Committee on a communication from the Council of the British Medical Association :—

Report by the Executive Committee on certain communications from the British Medical Association in regard to a proposed deputation on the subject of preliminary general education.

The committee on May 26th, 1902, received the following communications from the British Medical Association requesting the Council to receive a deputation on the subject of the preliminary general education of the medical profession.

(*a*)

"British Medical Association, General Secretary's Office,
"429, Strand, London, W.C., May 5th, 1902.

DEAR SIR,—At a meeting of the Council of the British Medical Association, held on Wednesday, April 16th last, a report was presented on the preliminary general education of the medical profession, and it was resolved that the General Medical Council be requested to receive a deputation on the subject.

I shall be glad if you will let me know when it will be convenient for the General Medical Council to receive the deputation.

I am, Sirs, yours faithfully,
The Registrar, General Medical Council. FRANCIS FOWKE.

The deputation to consist of the following:—The President (Dr. G. B. Ferguson), Cheltenham; the President Elect (Mr. Walter Whitehead), Manchester, the President of Council (Dr. J. Roberts Thomson), Bournemouth; the Treasurer (Mr. Andrew Clark), 71, Harley-street; Dr. T. Bridgwater, Framfield, Sussex; Professor J. W. Byers, M.D., Belfast, Mr. James Cantlie, 46, Devonshire-street, W., Professor D. W. Finlay, M.D., Aberdeen, Sir Walter Foster, M.D., M.P., 30, Grosvenor-road, Westminster, Mr. T. R. Jessop, Leeds, Mr. N. C. Macnamara, 21, Grosvenor-street, W.; Sir John Wm. Moore, M.D., Dublin, Dr. R. W. Philip, Edinburgh, Dr. F. M. Pope, Leicester; Dr. T. G. Roddick, Montreal, Dr. Markham Skerritt, Clifton; Mr. T. Jenner Verrall, Brighton, Dr. Maury Deas, Exeter, Mr. W. F. Haslam, Birmingham; Mr. Victor Horsley, F.R.S., 25, Cavendish-square, W.; Dr. C. H. Milburn, Hull; and Mr. Jones Morris, Portmadoc."

(*b*)

"British Medical Association, General Secretary's Office,
429, Strand, London, W.C., May 26th, 1902.

DEAR SIR,—In reference to my letters of the 5th and 22nd inst., I forward to you herewith a copy of the report that it is the desire of the deputation from the council of the Association to present to the General Medical Council. I am, yours faithfully,
FRANCIS FOWKE, General Secretary.
H. E. Allen, Esq., Registrar, General Medical Council."

"BRITISH MEDICAL ASSOCIATION.

REPORT OF THE PRELIMINARY EDUCATION COMMITTEE.

The Committee has come to the following conclusions:—

(1) That it is essential, in the interests both of the public and of the profession, that there should be an adequate guarantee that every registered medical practitioner has received a liberal education such as would entitle him to be regarded as a member of a learned profession.

(2) That at present, with the existing requirements of the General Medical Council and with the variations in the scope and standard of the various preliminary examinations for medical students, there is no such adequate guarantee.

(3) That the General Medical Council, by its action in 1898, recognised that the minimum standard of general education was too low and expressed its desire that it should be raised considerably, mentioning a standard of requirement represented by the senior local examinations of the several universities.

(4) That since the above date practically no progress has been made in the direction of adequately raising the standard of the examinations recognised by the General Medical Council.

(5) That this committee is of opinion that the time has come for the British Medical Association to take up this important subject and to use its power and influence towards obtaining the needed reform. With this view the committee makes the following recommendations:—

(*a*) That it is undesirable that anyone should be registered as a medical student until he or she has attained the age of 17.

(*b*) That the standard of the examination in preliminary general education required by the General Medical Council should be suitable for candidates of 17 years of age, and not lower than that required at present for the Oxford or Cambridge Senior Local Examinations.

(*c*) That the examination should include a pass and an honours division as in the university local examinations, the subjects for the pass to comprise at least Latin, mathematics (comprising arithmetic, algebra, and geometry); English grammar, literature, and essay writing; history; geography; and either French or German; honours division to include Greek and physical science as comp subjects.

(*d*) That the present system of multiple examining board undesirable and that it is essential in order to secure un standard that the Medical Acts should be amended so th Medical Council should be empowered to appoint a si board, which should hold its examinations as often multiple centres simultaneously.

(6) That a copy of this report be forwarded to th Council and that the General Medical Council be deputation from the Council of the British Med order to confer with them on this important matte
429, Strand, W.C., May 10th, 1902."

It was resolved.—In view of the facts (1) th preliminary general education of medical studen been under the careful consideration of the important steps have recently been taken object of raising the standard of such ed regulations on this behalf came into forc (4) that there has not yet been sufficie changes to produce their full effect, th opinion that it would not be opportu the present time, and are unable deputation should be received by th

As, however, it would appear from Education Committee of the Britis is unaware of the various report Council since 1898, the Executive of these should be forwarded to Association for their information

Mr. HORSLEY thought th unfortunately. It was certa of the facts with which the he therefore now wished to the deputation.

Sir CHRISTOPHER NIXON w Mr. Horsley substituted " "Council."

Mr. HORSLEY was willing to make this alteration.

On the suggestion of the PRESIDENT that the first thing to do was to put it on record that they received the report,

Sir JOHN BATTY TUKE moved :—

That the report be received and entered upon the minutes.

Mr. HORSLEY took exception to the last sentence of the report—that beginning with the words, "As, however, it would appear"—and he moved its deletion. He said that the sentence was not true and he did not wish that anything should go on to the Council's minutes that could not be substantiated

Dr. MACALISTER maintained that the sentence was quite in order. What the Executive Committee referred to in it were the following words of the memorialists: "(4) Since the above date practically no progress has been made in the direction of adequately raising the standard of the examinations recognised by the General Medical Council." He contended that the whole of the reports adopted since 1898 were in the direction of progress, and yet all of them appeared to be ignored by the words of the memorialists which he had just quoted. That being so he thought the Executive Committee was perfectly justified in submitting the sentence taken exception to.

Mr. HORSLEY did not think so. The subject, he explained, had been brought before the Council of the British Medical

Corlette, C. E., M.D. Syd., has been appointed Acting Honorary Assistant Surgeon to the Women's Hospital, Sydney, during the absence of Sir James Graham in Europe.

Davy, T. G., M.R.C.S., L.S.A. Lond., has been appointed Honorary Medical Officer to the Fremantle Hospital, West Australia.

Esson, E. G. Lyster, L. & L. Mid. R.C.P. Edin., has been appointed Officer of Health, Peak Hill, West Australia.

Evans, Arthur, M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to Westminster Hospital.

Greenwood, A., M.D. Vict., has been appointed Medical Officer of Health of Blackburn, vice Dr. James Wheatley.

Hall, James A. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer and Public Vaccinator of the Stoke Golding District of the Hinckley Union, vice Dr. B. J. Pritchard, resigned.

Hunter, Mitchell, M.D. Miami Med. Col., L.S.A. Lond., has been appointed Certifying Surgeon under the Factory Act for the Magherafelt District of the county of Londonderry.

Hunter, W. M., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory Act for the Crumlin District of Antrim.

Lister, Harold, M.B. Melb., has been appointed Acting Medical Superintendent of the Ararat Lunatic Asylum, Victoria, during the absence on leave of W. H. Barker, M.R.C.S. Eng.

Lloyd, F. S., M.B. Lond., has been appointed Certifying Surgeon under the Factory Act for the Luton District of Bedfordshire.

Macvie, A., M.D. Edin., has been re-appointed Medical Officer of Health by the Baildon Urban District Council, Yorks.

Mitchell, James Thomas, M.D., Ch M. Aberd., M.R.C.S., has been appointed Resident Medical Officer to the Ballarat Benevolent Asylum and Lying-in Home, Victoria.

McLean, J. C., M.B., C.M. Edin., has been appointed Medical Officer of Health by the Doncaster Rural District Council.

Mossop, A. G., M.R.C.S., L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Newhaven Port Sanitary Authority.

Nettle, William, M.R.C.S., L.S.A., J.P., has been re-appointed Medical Officer of Health by the Liskeard Rural District Council.

Nicholls, John Michael, L.R.C.P. Lond., M.R.C.S., J.P., has been re-appointed Medical Officer of Health of St. Ives, Cornwall.

Pallett, T. B., L.S.A. Lond., has been appointed Certifying Surgeon under the Factory Act for the Earl's Colne District of Essex.

Pearse, James, M.D., C.M. Edin., has been appointed Medical Officer of Health of Trowbridge, Wilts.

Reiach, James, M.B., M.S. Edin., has been appointed Government Officer and Vaccinator at Molong, New South Wales.

Saunders, Leonard Douglas, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Hastings, St. Leonards, and East Sussex Hospital, Hastings.

Shaw, A. H. P., M.R.C.S., L.R.C.P. Lond., has been re-appointed Medical Officer of Health of Frittenden.

Tayler, George Christopher, M.D., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the No. 3 District by the Westbury, Wilts, Board of Guardians.

Thomas, J. Telfer, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health for Camborne, Cornwall.

Watts, W. F., M.R.C.S. Eng., L.S.A., has been re-appointed Medical Officer of Health by the Dewsbury Borough Corporation.

Wheatley, J., M.D. Lond., has been appointed Medical Officer of the county of Shropshire.

Williamson, Oliver K., M.A., M.B., B.C. Cantab., M.R.C.P. Lond., M.R.C.S. Eng., has been elected Medical Registrar to the Middlesex Hospital.

Wohlmann, Arthur S., M.D., B.S. Lond., has been appointed Official Balneologist to the Government of New Zealand.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bethnal Green Infirmary.—Third Assistant Medical Officer. Salary £100 per annum, with apartments, board, and washing.

Bootle Borough Hospital, Liverpool.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence.

Central London Sick Asylum District.—Assistant Medical Officer. Salary £120 per annum, with board and residence.

City of London Union Infirmary.—Assistant Medical Superintendent, single, or widower without children. Salary £150 per annum, with apartments, rations, and washing.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, &c.

Cosford Union, Suffolk, Bildeston District.—Medical Officer and Public Vaccinator. Salary £72 per annum (exclusive of fees approximating to £78 per annum).

Cosford Union Workhouse, Suffolk.—Medical Officer. Salary £50 per annum, with fees.

Cumberland Infirmary, Carlisle.—Resident Medical Officer as House Physician for first six months and House Surgeon for ensuing six months. Salary at rate of £80 and £100 per annum respectively, with board, lodging, and washing.

Durban, Natal, South Africa.—Medical Officer of Health. Salary at rate of £750 per annum.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Electrical Department.

East Sussex County Asylum, Hayward's Heath.—Second Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, washing, and attendance.

Herefordshire General Hospital.—Assistant House Surgeon. Salary £55, with board and residence.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium £25.

Hospital for Women, Soho-square.—Clinical Assistants.

Jewish Mutual Birmingham Benefit Society, Bow-road, E.—Medical Officer.

Kent and Canterbury Hospital.—Surgeon.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

Liverpool County Asylum, Rainhill.—Assistant Medical Officer, unmarried. Salary £150 per annum, with prospect of increase, with apartments, board, attendance, and washing.

Liverpool Infirmary for Children.—Assistant House Surgeon for six months. Salary £25, with board and lodging.

Liverpool Stanley Hospital.—Third House Surgeon. Salary £70 per annum, with board, residence, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeon, under the Factory Acts, at Portaferry, in the county of Down; at Cushendall, in the county of Antrim, at Blisworth, in the county of Northampton; at Hutton Thornes, in the county of Yorkshire; at Caton, in the county of Lancashire, at Epping, in the county of Essex; at Dromore, in the county of Down; at Scotstown, in the county of Monaghan; at Clay Cross, in the county of Derby; at Alfreton, in the county of Derby; at Saddleworth, in the West Riding of the county of York, and at Chipping Sodbury, in the county of Gloucester.

Births, Marriages, and Deaths.

BIRTHS.

Meakin.—On March 25th, at Cambridge, the wife of Captain Harold Meakin, M.D. Lond., Indian Medical Service, of a son.

Powell.—On March 25th, at The Cottage, Bagshot, the wife of Major Simpson Powell, M.D. Durh., Royal Army Medical Corps, of a daughter.

MARRIAGES.

Addison—Gray.—On Tuesday, March 25th, at Trinity Presbyterian Church, Kensington-park-road, by the Rev. Hugh Falconer, M.A., B.D., Christopher Addison, M.D., F.R.C.S., youngest son of the late Robert Addison, senior, of Stallingboro, Lincolnshire, to Isobel, youngest daughter of the late Archibald Gray, of 37, Holland-park, W., and of Mrs. Gray, St. Mary's Tower, Birnam, Perthshire.

Barnby—Davison.—On April 2nd, at the parish church, Stokesley, Yorkshire, by the Rev. J. Groves, vicar of Redcar, Wm. Henry, L.R.C.P. & S., youngest son of the late John Eager Barnby, Great Yarmouth, to Hilda, second daughter of the late Robert Davison, Southfield Villas, Middlesbro.

DEATHS.

Brown.—On March 28th, at Newlands, Crawley Down, Sussex, Robert Brown, F.R.C.S., in his 62nd year.

Bryant.—On March 22nd, at San Remo, in his 43rd year, Sidney William Bryant, M.D. Edin., M.R.C.S.

Fox.—On March 28th, at Clifton-park, Bristol, Edward Long Fox, M.D. Oxon., F.R.C.P. Lond., aged 70 years.

Preston.—On March 16th, at 4, Abercorn-place, N.W., William John Preston, Esq., M.D., aged 62 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Association by practitioners in the West of England, who formed a committee in their own district, who had passed resolutions which were practically embodied in the report just read, who were intimately acquainted with every single fact in all the reports of the General Medical Council, and who had carried out a careful and minute study of these reports. To adopt such words as he was taking exception to was therefore almost an insult to them. It would be seen that in writing as they had done they had in view not the members f *the General Medical Council* but the members of the *association to which* they belonged and he considered that in he general statement made they were absolutely accurate. here was no proof that the standard of preliminary general ducation had been raised at all and therefore the memoialists were perfectly justified—more than justified—in the tatements submitted to the Council and the sentence he bjected to should not be passed, because these gentlemen of he West of England were as well acquainted with the facts s the members of the Council were themselves.

Mr JACKSON seconded the proposal.

Mr BROWN opposed the amendment on the ground that he entire report should go upon the minutes as a historical ecord of the Executive Committee's expression of their view egarding allegations of a body representing the medical rofession

Sir JOHN BATTY TUKE said that they had only Mr orsley's word for it that the memorialists understood the uestion, because there was evidence in the matter of the ocument as well as in the terminology employed which howed that they were in a most extraordinary state of gnorance. They had ignored the history of the last 40 years, hey had ignored the fact that when the Council was consti*uted the condition of preliminary examinations comparatively* with those of to-day was far from satisfactory Gradually he General Medical Council had been able to put pressure on the various examining bodies, with the result that a certain amount of *efficiency had been attained to, but during* the last 10 years the Council had taken steps which, he believed, would produce very important results indeed, But what struck him most of all was that the memorialists had not been able to extract from the reports they were said to have examined the fact that the Council and its Education Committee had found it impossible in present circumstances to raise the standard of preliminary general education higher than it was at present because of the risk of depleting the *profession* to the serious danger of the public. He could assure them that everything possible had been done in the direction of progress. They had consulted the highest authorities on education; they had considered and re considered and had gone as far as the inchoate condition of general education in England, and especially secondary education, would allow them to go. Now and improved methods had come into operation this year, but the Council could not tell at once what would be the result of them. They would need to wait two or three, perhaps four or five, years to ascertain what the effects would be, but they had to do something more. they must wait to see what would be the results of the Education Bill at present before Parliament—a Bill that must necessarily do a great deal towards the improvement *of secondary education* in this country That was a matter which the General Medical Council could not force, therefore his feeling was that the Council of the British Medical Association in coming to the conclusion put forward in its resolutions had on this occasion ignored the main fact—namely, that the General Medical Council had gone as far as it could in the present circumstances.

Dr ATTHILL *said that as a member of the Executive* Committee he had agreed to the sentence objected to which ad been passed after due consideration and deliberation e personally know that the standard of preliminary ation in Ireland had been raised very considerably and d think that the memorialists had not been fully aware had been done by the Council when they framed their *ntation.*

MCVAIL pointed out that it would serve no purpose to strike out of the *Executive Committee's* report fore the Council the sentence taken exception to, even though struck out of that report it would s part of the minutes of the Executive Committee, open to the public, being bound up along with of the General Council. In the matter of form tly he must oppose the amendment.

RSLEY, because of what Dr McVail had just said, asked leave to withdraw the amendment. He, however, asked to be allowed to reply to Sir John Batty Tuke.

The PRESIDENT ruled that this would not be in order

Mr HORSLEY hoped that in these circumstances Sir John Batty Tuke would *repeat his statements before the next* meeting of the British Medical Association.

Dr MACALISTER wished to emphasise this, that the standard of preliminary examination in general education for medical students had been very much raised indeed, as any member of Council could ascertain *for himself* on inquiry He held in his hand at that moment a document relating to the examination instituted by the College of Preceptors which showed that while 47 candidates presented themselves for examination only six were able to fulfil the requirements. That, he thought, *would be repeated very generally so soon* as the new regulations were enforced Outsiders like the memorialists could not possibly have the means of knowing what the result of the steps taken by the Council was going to be, *therefore he gave no weight whatever to the opinion* passed on that matter by the memorialists.

The motion that the report should be received and entered on the minutes was then adopted.

Mr HORSLEY thereupon moved—

> That the Education Committee receive on behalf of the Council the deputation from the Council of the British Medical Association on the subject of the preliminary general education of medical students

He said that he was glad he had brought forward *this matter* because it had extracted valuable information. Over and over again they had been told that the Education Committee was in possession of information which was not given to the Council itself That had been repeated in the course of this discussion and consequently he thought that if they had the memorialists before them to tell what they did know the Council would be doing a service not only to the general public but also to the profession. All the memorialists asked was that the Council *should confer with them on the subject. They simply wished* to inform the Council as to their views of what the profession thought in regard to the standard To say that the Council would not receive them because they did not know what they did know was absurd Their reception would not take more *than one* and a half hours of the time of the Education Committee and as the proceedings would be reported they would be instructive to the world at large.

Sir CHRISTOPHER NIXON, as a member of the Education Committee, thoroughly endorsed *the view that that com*mittee had gone as *far as it could go at the present time* in raising the standard of preliminary education, but when they had a body like the British Medical Association asking *them to* confer on the subject it seemed to him that it would be wanting in courtesy on the Council's part to refuse to receive a deputation. An interview, he believed, would be advantageous in showing the Association that the Council had endeavoured to raise the standard as high as present conditions allowed

Sir JOHN BATTY TUKE regarded the reasons given in support of the requested interview as being so much opposed to the action of the Council that it seemed impossible to receive a *deputation.* Impossibilities were asked for. Changes were wanted that could not be got without legislation and the Council knew *how* difficult it was to secure legislation With regard to the Education Committee having information which it had not given to the Council the committee certainly had been entrusted with the opinion of *experts on the* subject, but it was impossible to disclose such opinions. It had information on which it acted which *could* not be made public, but apart from that it had done every*thing it could* in the direction of securing progress He should regard the passing of Mr Horsley's motion as a vote of censure on the Education Committee.

Several Members Nothing of the kind.

Dr WINDLE would be the last man to pass a vote of censure on the Education Committee At *the same time* he should certainly regret if the Council refused to accept Mr Horsley's motion, and he thought that Sir John Batty Tuke should rather rejoice at the opportunity it would afford *him of having* the apostolic chance of dispelling the ignorance that it was alleged existed So far as he himself was concerned, he believed that the preliminary education for medical students *at the present* time was inadequate, still the state of affairs as regarded general education was not at all satisfactory Improvement was necessary, *and they were screwing up the* schools to secure better teaching power That process of screwing meant time and meant waiting to see results Such a fact should be stated to the proposed deputation, as it would be of great advantage to the profession and the public. He should vote for Mr. Horsley's proposal, but in no sense could he consider it a vote of censure on the Education Committee.

Dr. PAYNE expressed the same view of the proposal. He thought that the deputation should be received, not by the Council, but by the Education Committee.

Mr. TOMES was of the opinion that though they did not agree with all that the communications before them contained, it would be hardly the right thing for the General Medical Council—a body representing the medical profession—to decline the reception of a deputation which was to be headed by the principal office-bearers of the largest medical association in the world.

After some further remarks Mr. Horsley's motion was adopted.

The PRESIDENT pointed out that a number of the gentlemen named on the list resided far distant from London—there was one in Montreal and several in the West of England—and he supposed that time would have to be given to afford them an opportunity of attending. Moreover, he did not know whether all the gentlemen named had consented to allow themselves to be included, for instance two members of the General Medical Council were amongst them—namely, Dr. Finlay and Mr. Horsley. He did not know whether they had consented.

Dr. FINLAY: My name was put on this list without my knowledge, and I do not propose to attend as a member of the deputation.

Mr. HORSLEY: I received a request to attend as a member of the deputation, and I said I would do so.

It was arranged that in correspondence with Mr. Fowke the Education Committee should arrange the time for receiving the deputation.

The Council adjourned.

WEDNESDAY, MAY 28TH.

The Council resumed to-day, with Sir WILLIAM TURNER in the chair.

The Case of Marcus Robert Phipps Dorman.

For over two hours the Council sat *in camerâ* hearing and deliberating on the case of Dr. Marcus Robert Phipps Dorman of 9, Norfolk-crescent, Hyde Park, London, W., registered as M.B., Bac. Surg. 1892, Dip. Public Health 1893, M.D. 1899, Univ. Camb., Mem. R. Coll. Surg. Eng. 1892, Lic. R. Coll. Phys. Lond. 1892, who had been summoned to appear before them on a charge of unprofessional conduct. On strangers having been re-admitted, Dr. Dorman was called upon.

The PRESIDENT addressing him said: The Council has carefully deliberated on your case and they have instructed me to announce to you the resolution at which they have arrived: "That the Council do now judge you to have been guilty of infamous conduct in a professional respect and do direct the Registrar to erase your name from the Register." That is the decision of the Council.

The Case of John Flanagan.

Consideration was next given to the case of John Flanagan, of Patrick's-terrace, Castlerea, co. Roscommon, registered as Lic. R. Coll. Phys. Edin. 1900, Lic. R. Coll. Surg. Edin. 1900, Lic. Soc. Phys. Surg. Glasg. 1900, who was convicted on March 5th last at a general assize of the peace at Longford, Ireland, of throwing upon a man named Phillips a certain corrosive fluid with intent to do him injury, and was sentenced to a year's imprisonment.

Mr. WINTERBOTHAM (solicitor to the Council) stated that earlier in the day he had received a letter from Flanagan's solicitor asking postponement of the case in order that Flanagan might have an opportunity personally to appear before the Council. A petition on his behalf had been sent to the authorities, and the writer of the letter expressed the belief that his client would be released from custody in a very short time.

After the case had been deliberated upon *in camerâ*,

The PRESIDENT said: I have to announce that Mr. John Flanagan having been proved to have been convicted of felony, the Registrar has been directed to erase his name from the Medical Register.

The Case of Edward Thomas Ffrench.

The Council proceeded with the case of Edward Thomas Ffrench of Glasson, co. Westmeath, registered as Lic. 1862, Lic. Midwif. 1863, Fell. 1874, R. Coll. Surg. Irel., Lic. Med. Univ. Dubl. 1863, who at the Westmeath Summer Assizes held at Mullingar on July 1st, 1901, was found guilty of manslaughter and was sentenced to penal servitude for life.

The PRESIDENT, after a short sitting *in camerâ*, said: I have to announce that Edward Thomas Ffrench having been convicted of a felony, the Council has directed the Registrar to erase his name from the Medical Register.

The Case of Samuel Marston.

Consideration was next given to the case of Samuel Marston, dentist, registered as of 282, Belgrave-gate, Leicester, "in practice before July 22nd, 1878," who at the Hereford Assizes in November last was convicted of bigamy and was sentenced to 18 months' imprisonment with hard labour.

Mr. WINTERBOTHAM informed the Council that very shortly before he had received from Marston's brother an appeal for postponement of the case so as to allow Marston to appear before the Council himself "to be censured for the past and threatened for the future."

This document with others was considered in private, and then—

The PRESIDENT said: I have to announce that Samuel Marston having been proved to have been convicted of a felony, the Registrar has been directed to erase his name from the Dentists' Register.

Returns of Professional Examinations.

Mr. BALL moved:—

> That it be referred to the Examination Committee to report whether it is desirable to obtain from the various licensing bodies the following additional information for use in the preparation of the annual table (a) showing results of professional examinations:—
>
> 1. Where credit is allowed for a single subject or group of subjects only at any examination the number of students who pass or are rejected in such portion of the examination should be furnished separately from the list of those who pass or are rejected from the entire examination.
>
> 2. That in addition to giving a return of the candidates rejected at any examination the number of such candidates who have been previously rejected upon one or more occasions for the same examination be indicated, with the number of such previous rejections in each case.

In supporting this proposal Mr. Ball explained that the object of the first part of his motion was to secure that the table in question should be a more accurate record than it was at present, and should show whether "passes" returned were passes of the complete examination or only a certain portion of it. With regard to the second part of the motion he thought that some scheme might be devised which would stop the "chronic" student at an earlier part of his career, and in order to further that they should have information as to what proportion of the students rejected at a certain examination had previously been rejected on going up for the same examination. He thought that it would do good if on a first rejection a student was debarred from going up again for six months, on a second for 12 months, and on a third for a longer period. If the licensing bodies would agree to adopt some such scheme generally a very great step would be made in excluding the chronic student at an earlier stage than it was possible to do at present.

Mr. HORSLEY, who seconded, said that it was most desirable that they should have the annual tables complete.

Sir CHRISTOPHER NIXON remarked that the motion opened up for the consideration of the Council or its Examination Committee the very important question of uniformity of standard of examination. At present there was no uniformity, the different medical licensing bodies having varying systems, some giving no credit unless the complete examinations were passed and others giving credit where only a certain portion was passed. If the motion secured sameness in the conduct and standard of examinations that would be very satisfactory.

Dr. NORMAN MOORE thought that the information wanted was of a kind that might be very well obtained. All the information that it was possible to get the Council should have before it, and he thought that there could be no hesitation on the part of any of the licensing bodies to furnish what was now desired.

The PRESIDENT said that it seemed to him that the first part of the motion started on an assumption that generally allowance was made for a single subject or group of subjects, and that students were returned as passing or being rejected not in the whole examination but in a portion of it. Now, he thought that the Council or the Examination Committee should satisfy itself that returns were framed on that basis. As regarded the University of Edinburgh returns were not made on that basis. If a man was returned as having passed, that meant that he must have passed all the subjects of the examination. However, the question here raised was one of the returns made to the Council by the respective registrars of the licensing bodies, and he must say the motion was so framed that if sent down to the bodies in the form in which it now stood it would be differently interpreted by different bodies. He thought that it needed redrafting, and he suggested that the Examination Committee should be allowed to work it into a shape that would make it clear to all who would have anything to do with it.

The motion having been agreed to,

Mr. **BRYANT** assured the Council that the Examination Committee would try to make it clear.

The Council adjourned.

THURSDAY, MAY 29TH.

The Council met again to-day and proceeded with the consideration of more penal cases.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the diploma of Fellow at the half-yearly meeting of the Board of Examiners in May:—

Philip Edward Homer Adams, B.A. Oxon., Oxford University and London Hospital; Robert Aird, M.B., Ch.B. Aberd., Aberdeen University; George Arthur, M.B., Ch.B. Glasg., Glasgow University and King's College, London; John Gerald Atkinson and Tom Bates, St. Bartholomew's Hospital; Athelstan Jasper Blaxland, University College, London; Frederick Barnes and John Hunter Clatworthy, Guy's Hospital; Frank Coleman, M.R.C.S. Eng., L.R.C.P. Lond., Charing Cross, King's College, and St. Bartholomew's Hospital; Albert William Duncan Coventon, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Henry Tregellas Doble, M.R.C.S. Eng., L.R.C.P. Lond., St. Mary's and King's College Hospitals; Richard Felton, Guy's Hospital; Cecil Irving Graham, M.R.C.S. Eng., L.R.C.P. Lond., St. Mary's Hospital; Philip Maynard Heath, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., University College, London; Henry Thomas Hicks, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; Ernest Cranmer Hughes, B.A. Camb., Cambridge University and Guy's Hospital; Frank Alexander Jeans, B.A. Camb., Cambridge University and King's College, London; John Frederick Jennings, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's and King's College Hospitals; William Lowe, B.A. Camb., Cambridge University and London Hospital; Thomas Lyle, Queen's College, Belfast; Donald Johnstone McGavin, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Birmingham University; James Cole Marshall, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; William Mayhew Mollison, B.A. Camb., Guy's Hospital; Sydney Arthur Owen, B.A. Camb., Cambridge University and King's College, London; Charles Buckingham Shuttleworth, M.D., C.M. Toronto, M.R.C.S. Eng., L.R.C.P. Lond., Trinity College, Toronto, and King's College, London; Richard Atkinson Stoney, M.B., B.Ch., B.A. Dub., Trinity College, Dublin; Charles Bertram Thomson, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; William Traill Thomson, Otago University and King's College, London; Frank Edward Taylor, M.A., M.B., M.Sc. Vict., M.R.C.S. Eng., L.R.C.P. Lond., Yorkshire College, Leeds, and King's College, London; Gordon Wilson Thomas, Yorkshire College, Leeds; Tom Walker, M.R.C.S. Eng., L.R.C.P. Lond., Owens College, Manchester; John Benjamin Valentine Watts, University College, Bristol; Kenrick Stanton Wise, B.Sc. Lond., St. Bartholomew's Hospital; Cyril George Russ Wood, M.R.C.S. Eng., L.R.C.P. Lond., University College, Bristol; Ernest Eric Young, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital.

183 gentlemen presented themselves for this examination; the above-named 35 passed, while 88 gentlemen were referred to their studies for six months.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in May the following candidates passed in the subjects indicated:—

Surgery.—P. G. Bennett (Sections I. and II.), Cambridge and University College Hospital; J. C. O. Bradbury (Sections I. and II.), Cambridge and Guy's Hospital; G. F. G. de Laubenque, Middlesex Hospital; H. F. B. Roberts (Sections I. and II.) and B. Rowlands, St. Bartholomew's Hospital; and P. P. Tobit (Section II.), King's College Hospital.

Medicine.—J. H. Clements, Birmingham and University College Hospital; E. Gray, London Hospital; W. P. A. Hardwicke, Durham; G. A. Jones (Sections I. and II.), St. George's Hospital; F. I. M. Jupe, Cambridge; E. J. Miller, King's College Hospital; H. F. B. Roberts (Sections I. and II.), St. Bartholomew's Hospital; F. H. Rotherham, London Hospital; and C. M. Woods (Section I.), Charing Cross Hospital.

Forensic Medicine.—E. Gray, London Hospital; G. A. Jones, St. George's Hospital; F. I. M. Jupe, Cambridge; E. J. Miller, King's College Hospital; F. H. Rotherham, London Hospital; and C. M. Woods, Charing Cross Hospital.

Midwifery.—C. A. Crowe, London and Westminster Hospitals; G. A. Jones, St. George's Hospital; and F. H. Hand, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: J. H. Clements, W. P. A. Hardwicke, F. I. M. Jupe, G. F. G. de Laubenque, B. Rowlands, and P. P. Tobit.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

Miss C. McCrea, Mr. R. D. Patterson, Mr. R. S. Ryce, Mr. M. J. Smith, and Mr. D. Turner.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne*: Dr. Leon Ascher, *privat-docent* of Physiology, and Dr. Max Howald, *privat-docent* of Pathological Anatomy, have been granted the title of Professor.—*Bonn*: The title of professor has been granted to Dr. Pletzer and to Dr. Wendelstadt.—*Halle*: Dr. Heilbronner, *privat-docent* of Neurology and Psychiatry, has been promoted to an extraordinary professorship.—*Munich*: The charge of the Hygienic Institute has been temporarily entrusted to Professor Rudolf Emmerich until a successor to the late Professor Buchner is appointed.—*Naples*: Dr. Carmelo Abate has been recognised as *privat-docent* of Laryngology.—*Pennsylvania*: Dr. Geo. E. de Schweinitz has been appointed to the chair of Ophthalmology.—*Vienna*: Dr. Wilhelm Latzko has been recognised as *privat-docent* in Midwifery and Gynæcology.

VACCINATION FEES.—The Plympton (Devon) Board of Guardians on May 16th decided to support the resolution of the Rugby Guardians and to petition the Local Government Board to amend the Vaccination Order by providing that the fees for revaccinations at the homes of the persons vaccinated should be the same as for revaccinations performed elsewhere—viz., 2*s.* 6*d.* instead of 5*s.* The guardians also recommended that the Government should undertake the gratuitous supply of lymph to private practitioners.—The Barnstaple (Devon) Board of Guardians at their meeting on May 16th also decided to support the petition of the Rugby Guardians.—At the meeting of the Tavistock (Devon) Board of Guardians held on May 17th a motion was passed urging the suggestion that persons who desired to be revaccinated should attend the house of the public vaccinator or a station appointed for that purpose, otherwise they should themselves defray the cost of revaccination at their own homes.—The Devonport Board of Guardians on May 23rd and the Wellington (Somerset) Board of Guardians at the meeting on May 22nd also decided to support the memorial of the Rugby Board of Guardians.

ROYAL METEOROLOGICAL SOCIETY.—The first of the afternoon meetings of the session of this society was held at the society's rooms, 70, Victoria-street, Westminster, on May 21st., Mr. W. H. Dines, B.A., the President, being in the chair. Captain D. Wilson Barker read a report prepared by Mr. Dines and himself on the Wind Force Experiments which had been made on H.M.S. *Worcester* off Greenhithe and at Stoneness Lighthouse, 817 yards from the ship on the north bank of the river. Dr. H. R. Mill read a paper on the Cornish Dust Fall of January, 1902. When the West of England newspapers of Jan. 24th announced falls of "pink snow" and "muddy rain" in several parts of Cornwall and South Wales it seemed to Dr. Mill possible that fresh light might be thrown on what was at present the chief object of progressive meteorology—viz., the movements of the upper air. He therefore took steps to collect as much information as possible from the whole of the district, and found that the phenomenon was reported from 75 different places in the south-west of England and Wales. These were all south of a line joining Milford Haven and Chepstow and west of the meridian of Bath. By means of a map Dr. Mill showed that four separate areas were visited by the dust between Jan. 21st and 23rd—viz.: (1) Cornwall, 1400 square miles; (2) North Devon, 150 square miles; (3) Milford Haven, 60 square miles; and (4) Bristol Channel, 600 square miles. The dust appeared to have been confined mostly to low rather than high ground, for none was reported to have fallen on the Mendip Hills, Dartmoor, Exmoor, and the Welsh mountains. The observations showed that Jan. 22nd was undoubtedly the day when most falls occurred and that the colour of the dust was yellowish or brownish. From a consideration of the meteorological conditions at the time and for several days before Dr. Mill was inclined to believe that the evidence pointed to the dust having been transported in the upper air from the African deserts.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—The provincial meeting of this society will be held at the Pendlebury Children's Hospital, Manchester, on Friday, June 20th, at 4 P.M. The proceedings should prove interesting judging from the list of communications which have been promised and which will be set out in our diary. At the conclusion of the meeting the members and their friends will dine at the Queen's Hotel. For the following day an excursion into Derbyshire has been arranged and those who intend to be present are requested to communicate with Dr. George Carpenter, 12, Welbeck-street, London, W., as soon as possible. The annual general meeting of the society will be held at the Hotel Cecil on July 16th, at 6.45 P.M., and will be followed by dinner at 7.30 P.M.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—The annual report of this institution for the year ending Dec. 31st, 1901, states that the in-patients numbered 1284, an increase of 101 on the previous year, which had been the highest yearly number on record. The average daily number of patients was 47. Four patients died, three of whom were admitted in a moribund condition. In the out-patient department 1026 women were delivered. There were three deaths, two from hæmorrhage before delivery and one from septicæmia. The expenditure for the year amounted to £5090, being £875 in excess of the ordinary income and an increase of £450 on the amount for the year 1900, accounted for partly by increases in the cost of provisions and other necessaries and partly by the additional number of patients. The ordinary income amounted to £3836, which is an increase of £592 on that of the previous year.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty of Medicine was held at the University on May 23rd, Mr. H. T. Butlin, the dean of the faculty, being in the chair. The faculty had under consideration the regulations for the matriculation examination recently approved by the Senate to which attention has already been drawn in THE LANCET. Under these regulations, in addition to English and elementary mathematics, which must be taken by all students entering for the examination, there is a large number of optional subjects, of which three must be chosen, one of the three being either Latin or a branch of elementary science. A proposal had been made that the Senate should publish in the University Calendar "advice to students as to the optional subjects they should select, having in view the faculty in which they intend to proceed to a degree." The Faculty of Medicine was asked whether it desired to indicate the optional subjects which should be chosen by a student preparing to obtain a degree in medicine. The following motion was passed:—

> In the opinion of the Faculty of Medicine it is undesirable that any official advice should be published in the Calendar of the University as to the optional subjects which should be taken at the matriculation examination by intending undergraduates in medicine.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held at 11, Chandos-street, London, W., on May 21st. The President, Mr. Christopher Heath, took the chair. The meeting was well attended. From the report read by the secretary it appeared that 35 new members were elected during 1901; 14 had died and two elections had been declared void; 299 members were on the books at the end of the year, an increase of 19. Six fresh applications for grants had been received from widows and the grants had been given. Two widows had died, leaving 51 in receipt of grants. Three orphans had been elected; two had become ineligible; 14 still remained for assistance. The receipts available for grants and expenses had been £3409 7*s* 6*d*. and the grants and expenses had been £3397 6*s* 2*d*. A donation of £200 had been received from the executors of the late Miss C. A. Birch. During the year Mr. J. R. Upton resigned the office of honorary solicitor which had been held successively by his father and grandfather. The directors had passed a cordial vote of thanks to Mr. Upton for his long and valuable services and had since heard of his death with great regret. Mr. H. G. Tudor was elected an honorary member. Mr. Tudor's family have acted as brokers since the foundation of the society and have always given their services gratis. A vote of thanks to the editors of the medical journals for their ready help in making known the objects of the society was passed. The following were elected to fill the vacancies in the court of directors: Mr. R. Debenham, Mr. J. B. Crozier, Dr. J. B. Constable, Dr. H. C. Pope, Dr. F. de H. Hall, Mr. F. Canton, Dr. J. Crabb, Mr. H. W. Kiallmark, and Dr. Scanes Spicer. A letter was read from Dr. Robert Barnes inclosing a donation of £100 and a cordial vote of thanks was accorded to him. A vote of thanks to the chairman closed the business of the meeting.

FREEMASONRY.—*Middlesex Hospital Lodge, No. 2848.*—The installation meeting of this Lodge was held at Freemasons' Hall on May 15th, when Bro. William Duncan, M.D., was installed Worshipful Master for the ensuing year. In the unavoidable absence of the Director of Ceremonies his place was ably filled by Bro. Vincent Cotterell. The Worshipful Master appointed as his principal officers Bro. F. J. Wethered, S.W., Bro. A. G. R. Foulerton, J.W., Bro. Henry Morris, Treasurer, Bro. F. Clare Melhado, Secretary. Mr. John Glenton Myler was initiated into Freemasonry. At the banquet which followed over 70 brethren and their guests were present. The retiring Master, W. Bro. T. G. A. Burns, on being presented with a Past Master's jewel, returned thanks to the brethren, saying what a great happiness it had been to him to preside as the First Worshipful Master of the Lodge.—*Cheselden Lodge, No. 2870.*—A Lodge of Emergency was held on March 14th, at which Bros. T. W. Buckley, P. W. Sargent, J. G. Turner, and H. G. Toombs were admitted to the second degree. At a regular meeting on March 21st the Worshipful Master, W. Bro. Thomas Wakley, Jun., admitted Bros. F. G. Parsons, H. O. Crouch, E. M. Corner, and W. F. Umney to the third degree and Messrs. L. A. R. Wallace, W. H. Battle, H. T. D. Acland, and H. S. Sington were initiated into Freemasonry. A Lodge of Emergency was held on April 18th for the purpose of admitting Bros. Buckley, Sargent, Turner, and Toombs to the third degree and Bros. L. A. R. Wallace, Battle, Acland, and Sington to the second degree. At a regular meeting held on May 16th Messrs. E. A. Gates, Z. Mennell, and Arthur Mead were initiated and Bros. L. A. R. Wallace, Battle, Acland, and Sington were admitted to the third degree. Bro. C. G. Seligmann and Bro. J. R. Beale were elected as joining members of the lodge. W. Bro. G. Crawford Thomson was unanimously elected Worshipful Master for the ensuing year. The sum of 20 guineas was voted to the Royal Masonic Institution for Boys to be placed on the list of the Worshipful Master who is representing the lodge as a steward at the forthcoming festival. A magnificent banner has been presented to the lodge by Bro. J. G. Wainwright, Treasurer of St. Thomas's Hospital, the first initiate of the lodge. The Worshipful Master of the Cheselden Lodge (for the time being) has been elected an honorary member of the following seven medical lodges: Rahere, Sancta Maria, Æsculapius, Cavendish, Middlesex Hospital, Chére Reine, and London Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Bill.

ACCORDING to the new rules of procedure now in operation two Fridays after Whitsuntide, the third and the fourth Friday after Whit Sunday, are reserved for Bills promoted by private Members and consequently it comes about that the consideration of the Midwives Bill as amended by the Grand Committee stands as the first order of the day for the sitting on Friday, June 6th. There will therefore be ample time for the discussion of the short list of amendments of which notice has been given.

HOUSE OF COMMONS.

MONDAY, MAY 26TH.

Uncertified Deaths in the Scottish Highlands.

Mr. WEIR asked the Lord Advocate if he would state the number of uncertified deaths in each of the six Highland crofting counties; and, in view of the fact that there was no information in the registrar's office as to the number of interments without the production of a medical certificate, would such steps be taken as would admit of this information being available.—The LORD ADVOCATE replied: The number of uncertified deaths in each of the crofting counties in 1900 was as follows: Shetland, 224; Orkney, 80; Caithness, 51; Sutherland, 104; Ross and Cromarty, 420; Inverness, 425; and Argyll, 175. The further information desired by the honourable Member cannot be obtained without legislation, which at present I cannot promise.

Lamp Accidents.

Mr. H. C. RICHARDS asked the Home Secretary (1) whether his attention had been called to the verdict of the jury as to the cause of the recent loss of life at the fire in Lever-street, St. Luke's, and whether the report of the London County Council on the occurrence had been brought before him; and (2) was he aware that five deaths had occurred in less than 12 months by the unrestricted use of American Tea Rose Oil in this district, and, if the Home Office were not prepared to take action, whether he would consider the advisability of additional powers being given to the London County Council to inspect and to regulate the sale of all dangerous American oils in the county of London.—Mr. Ritchie replied: I have had before me the verdict of the jury and the report of the Public Control Committee of the London County Council to which the question refers. In cases of accidents from defects in lamps or from the breaking of lamps it is a matter of great difficulty to decide in what way or to what extent the nature of the oil in use has occasioned or affected the accident; and I do not think that the suggestion at the beginning of the second paragraph of the question can be taken as a correct and sufficient statement of the causes of five, or indeed any, deaths in St. Luke's. Legislation would be necessary in order to bring under the control of a local authority petroleum not already so placed by the Acts of 1871 to 1881; and it is clear that such legislation would have to be of a general character, not confined to a particular locality. Moreover, I am not convinced that it would be effective in preventing or seriously diminishing the class of accidents in question or that there is sufficient justification for its introduction.

TUESDAY, MAY 27TH.

The Milk and Butter Question.

During the consideration of the vote for the Board of Agriculture several members called the attention of Mr. Hanbury to the working of the last Sale of Food and Drugs Act, that passed in 1899, which gives the Board of Agriculture, as well as the Local Government Board, certain powers as to adulteration. Sir Edward Strachey asserted that a great deal of milk was being sold in London to which large quantities of separated milk had been added along with colouring matter to conceal the adulteration, and he suggested that the central authority should send round inspectors to see that the local authorities were exercising proper supervision in this connexion. In his reply Mr. Hanbury said that there could be no doubt that in certain parts of the country the Act had not been carried out as efficiently as it might have been. The Act, however, was comparatively new and it would be well to leave local authorities a little more time to use their powers before the Board of Agriculture intervened. The department had two inspectors engaged in watching the effect and the extent of the operation of the Act; their reports kept him fully informed, and the only question was how long a period of grace should be allowed to local authorities who did not exercise their powers under the Act. His own feeling in regard to preservatives in butter and milk was that their use should be discouraged. As to the mixing of butter with other articles his view was that the farmer had a perfect right to his trade description and that articles ought not to be sold as butter which were not entitled to that description.

The Extermination of Rabies.

Mr. Hanbury also made a statement on this subject. He regretted the long retention of the muzzling order in certain districts but it had been found necessary owing to the continued presence of disease. He was not in favour of exemption even for sheepdogs. In the event of an outbreak of rabies he should not hesitate to issue a muzzling order without exemptions of any kind. No loophole should be left for the spread of a disease so terrible as rabies. A strong appeal was made in favour of the pet dog which was taken abroad and whose owner wanted to bring it back. This country, however, was now free from rabies with the exception of Carmarthen and part of the country round Plymouth. The continent, on the other hand, was not free from it. No precautions, therefore, could be too severe. The reason why the regulations were now more stringent than before was that the old regulation, whereby the owner of a dog was able to take his dog home on keeping it in quarantine for three months in his own house and not then allowing it to go loose until it was certified by a veterinary expert to be free from disease, had been grossly abused. The regulation had not been observed in cases. This was in itself good reason for the abolition of the privilege, and since the muzzling order had been withdrawn in so many places the case for the abolition had become much stronger. It seemed to him, when it was considered how many millions of people there were in this country to be kept free from the risk of rabies and how few people took their dogs abroad, the public health must be considered and not the convenience of that small body of persons.

Vaccination: Dr. S. A. M. Copeman's Experiments.

About one and a half hours were devoted to discussion on the vote for the Local Government Board.

Mr. Henry Broadhurst, the Member for Leicester, made complaint of the charges for vaccination. He thought that they were in many cases excessive and he suggested that the Local Government Board should issue regulations which would secure their reduction. He also complained that magistrates dealing with applications for exemption from vaccination often badgered and bullied those who came before them and said that he saw no reason why the Local Government Board should not issue instructions to protect parents in the exercise of the right conferred on them by the statute. Further, he asked the President of the Board to give an assurance that no more persons would be vaccinated with lymph derived from monkeys.—Mr. Thomas Bayley said that he desired to call the attention of the House to the action of Dr. S. A. M. Copeman, one of the servants of the Local Government Board. In a paper read before a medical society this gentleman stated that he had taken small pox virus from small-pox patients in Gloucester, or some other place where there had been an epidemic, and vaccinated monkeys and afterwards had taken vaccine from the monkeys and successfully vaccinated a great number of children. The President of the Local Government Board might laugh but the country regarded this matter in a very serious light. It was a disgrace for any Government department to allow one of its servants to do such a thing. The question he had to ask the right honourable gentleman was, whose children were they who were vaccinated with small pox taken through a monkey? Was the consent of the parents obtained before this experiment was made upon them? He had no doubt that this vaccine was issued with a sort of Government guarantee that it was pure vaccine.—Mr. Long, interrupting the hon. Member, said that he was indulging in the wildest suggestions. This lymph which he called small-pox given through a monkey had nothing on earth to do with the Local Government Board.—Mr. Bayley: But he was a Government servant and he was paid by the Government for these experiments.—Mr. Long: No, no. The hon. gentleman is probably not aware of the fact that a great many scientific gentlemen are employed by Government departments and that some of these gentlemen conduct for the public benefit experiments on their own account, and do a great deal of research work with which the Government department has nothing to do. Dr. Copeman did this particular research work, for which he has been thanked by the highest medical authority. He produced this lymph, though not in the remarkable manner suggested by the hon. Member, but the Local Government Board is in no way responsible for it. They do not condemn what he did. On the contrary, they believed that it was of the highest scientific value.—Mr. Bayley: But the Government paid him.—Mr. Long: The Government paid Dr. Copeman his salary as an inspector, but that does not prevent his engaging in research work in his own time.—Mr. Bayley: Will the right hon. gentleman tell me whose children were vaccinated?—Mr. Muntz: May I ask the hon. Member why he thinks a monkey is inferior to a calf?—Mr. Bayley: What I want to know is whether the lymph was used compulsorily to vaccinate children?—Mr. Long said that he would endeavour to deal with the complicated problem which the hon. Member had presented to the House. He had tried very hard in following the questions asked by the hon. Member in connexion with Dr. Copeman's experiments to find out what particular part in the puzzle the monkey was supposed to play but he had never yet succeeded in arriving at satisfactory information on the point. The hon. Member had told them that the whole country was moved to its very heart by this question but he (Mr. Long) could only say that with the exception of the hon. Member and one or two others he had met nobody who was in the least excited as to whether the monkey or the calf was used, not, as he said, for the purpose of conveying small pox either to the monkey or the calf. The process was really a simpler one than the hon. Member seemed to think. He was mistaken in thinking that the vaccine of the monkey passed directly to the child. It was passed through the calf, the safeguard to which the hon. Member apparently attached so much importance. Dr. Copeman conducted some extremely valuable experiments entirely upon his own account and he thought that the House would agree that it was undesirable that scientific men employed by the Government should be precluded from scientific research, which not only contributed to their own efficiency in their departmental work but to the great advantage of the public at large. Dr. Copeman made certain experiments. First of all Dr. Copeman vaccinated himself and having been satisfied that the lymph was not likely to produce injurious results he vaccinated the children of certain people with it. He (Mr. Long) was sorry he could not tell the hon. Member whose children they were but he assumed that the parents knew how the lymph had been obtained and were not at all disturbed by the monkey having played some part in its production. As to the charges of medical men for vaccination he could only say that when the Vaccination Act was passed the Government had no special experience as to what the working of it would be and he thought it was quite possible that he might have to reconsider the present payments made in respect of vaccination. As matter of fact he had the subject under consideration now. As to issuing a circular to magistrates indicating how they were to administer the law with reference to the conscientious objector, he could not undertake such a novel and undesirable course of action. The magistrates had before them the Act of Parliament and they were quite capable of interpreting it.

BOOKS, ETC., RECEIVED.

American Orthopedic Association, Chairman, Publication Committee, 372, Marlborough-street, Boston, U.S.A.

Transactions of the American Orthopedic Association. Fifteenth Session, held at Niagara Falls, June 11th, 12th, and 13th, 1901. Volume xiv. Price not stated.

Arnold, Edward, 37, Bedford-street, Strand, W.C.

A Text book of Physics. With Sections on the Application of Physics to Physiology and Medicine. By R. A. Lehfeldt, D.Sc., Professor at the East London Technical College. Price 6s.

Physiology for Beginners. By Leonard Hill, M.B., F.R.S., Lecturer on Physiology, London Hospital Medical School. Price 1s.

Baillière, J. B., et Fils, 19, Rue Hautefeuille, Paris.

Les Cures de Vichy: Indications, Régimes, Bains, Douches, Buvette, Exercice, Vichy et ses Environs. Par le Dr. Salignat, Médecin Consultant à Vichy. Price 2 francs.

Baillière, Tindall and Cox, 8, Henrietta-street, Covent Garden, W.C.

The Practitioner's Handbook of Diseases of the Ear and Naso-Pharynx. By H. Macnaughton-Jones, M.D., M.Ch., F.R.C.S. Irel. & Edin.; W. R. H. Stewart, F.R.C.S. Edin.; William Milligan, M.D., C.M.; Herbert Tilley, M.D., B.S., F.R.C.S. Eng.; Ambrose Birmingham, M.D., F.R.C.S. Irel., F.R.U.I. Irel.; and Robert Dwyer Joyce, F.R.C.S. Irel., M.R.C.S. Sixth edition. Price 10s. 6d. net.

Cassell and Company, Limited, London, Paris, New York, and Melbourne.

Clinical Methods: A Guide to the Practical Study of Medicine. By Robert Hutchison, M.D., M.R.C.P., and Harry Rainy, M.A., F.R.C.P. Edin., F.R.S. Edin. New, revised, and enlarged edition. Price cloth 10s. 6d.

Fischer, Gustav, Jena.

Bericht über die vom Komitee für Krebsforschung am 15. Oktober 1900, erhobene Sammelforschung. Herausgegeben von dem Vorstand. (I. Ergänzungsband zum Klinischen Jahrbuch. Im Auftrage des Königlich Preussischen Herrn Ministers der geistlichen, Unterrichts- und Medicinal-Angelegenheiten, unter Mitwirkung der Herren Prof. Dr. Kirchner und Dr. Naumann.) Price 10 marks.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Adams, A., M.A., M.B., has been appointed Medical Officer and Public Vaccinator for the No. 5 District of the Liskeard (Cornwall) Union.

Allbutt, Clifford, M.D., F.R.S., has been appointed Examiner in Medicine and Therapeutics for the Indian Medical Service.

Boger, William Henry, L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer and Public Vaccinator for the No. 4 District of the Liskeard (Cornwall) Union.

Bridger, J. F. E., M.R.C.S., L.R.C.P. Lond., has been appointed Civil Surgeon to the Troops and Boer Prisoners stationed at Antigua.

Brown, Major E. Harold, I.M.S., M.D., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Cowden, W. J., M.D. R.U.I., has been appointed Certifying Surgeon under the Factory Act for the Dromore District of the County of Down.

Cunningham, D. J., M.D., F.R.S., has been appointed Examiner in Surgical Anatomy and Physiology for the Indian Medical Service.

Hammond, William, L.R.C.P., L.M. Edin., M.R.C.S., L.S.A., has been re-appointed Medical Officer and Public Vaccinator for the No. 6 District of the Liskeard (Cornwall) Union.

Harding, Norman E., M.B., Ch.B. Edin., has been appointed Locum Assistant Medical Officer to the Durham County Asylum.

Leith, R. Calder, M.A., F.R.C.P. Edin., F.R.S. Ed., has been appointed Examiner in Pathology and Bacteriology for the Indian Medical Service.

Leonard, F. C., M.D., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Low, V. Warren, M.D., B.S., F.R.C.S., has been appointed Surgeon to the Out-patient Department of St. Mary's Hospital, Paddington.

MacCarthy, Brendan, M.D., B.Ch., B.A.O. Dub., has been appointed Permanent Medical Inspector on the staff of the Local Government Board at Londonderry.

Marsh, Howard, F.R.C.S., has been appointed Examiner in Surgery and Diseases of the Eye for the Indian Medical Service.

Murray, R. Milne, M.A., F.R.C.P. Edin., F.R.S. Ed., has been appointed Examiner in Midwifery and Diseases of Women and Children for the Indian Medical Service.

Powell, J. F., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the *Victoria Hospital*, Folkestone.

Provis, F. Lionel, M.R.C.S., L.R.C.P. Lond., has been appointed Registrar to the Chelsea Hospital for Women.

Rees, D. C., M.R.C.S., L.R.C.P. Lond., Senior Government Plague Medical Officer, Cape Colony, lately Medical Superintendent, London Tropical School of Medicine, has been appointed Medical Inspector on the staff of the Medical Officer of Health for the Cape Colony.

Stockman, Ralph, M.D., F.R.C.P., F.R.S. Ed., has been appointed Examiner in Chemistry, Pharmacy, Botany, and Zoology for the Indian Medical Service.

Waters, James, L.S.A. Lond., has been appointed Medical Officer of Health and Public Vaccinator to the Bildeston District of the Cosford Union, Suffolk, and Medical Officer to the Workhouse at Semer, Suffolk.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service, War Office, S.W.—Thirty Commissions.

Aylesbury, Royal Buckinghamshire Hospital.—Resident Surgeon, unmarried. Salary £80, rising to £100, with board and apartments.

Ayr District Lunacy Board.—Medical Superintendent. Salary £500, with house, coal, gas, &c.

Bethlem Hospital.—Two Resident House Physicians for six months, with apartments, board, &c. Honorarium at rate of £25 per quarter.

Birmingham and Midland Hospital for Skin and Urinary Diseases, Birmingham.—Clinical Assistant.

Bristol City Lunatic Asylum.—Medical Assistant, unmarried. Salary £140 per annum, increasing to £160, with apartments, board, and washing.

Central London Sick Asylum at Cleveland-street or Hendon.—First Assistant Medical Officer. Salary £120 per annum, with board and residence at Hendon Asylum.

Dudley Guest Hospital.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

Durham County Asylum.—Third Assistant Medical Officer. Salary £150, rising to £180 a year, with apartments, board, laundry, and attendance.

Fisherton Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

Forres Leanchoil Hospital, Morayshire.—Medical Officer. Salary £60 per annum.

GLASGOW ST. MUNGO'S COLLEGE, MEDICAL FACULTY.—Notman Chair of Physiology.

GRAVESEND HOSPITAL.—House Surgeon. Salary £90 per annum, with board and residence.

HORTON INFIRMARY, Banbury.—House Surgeon and Dispenser. Salary £80 per annum, with board and lodging.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence. Also Clinical Pathologist and Bacteriologist. Honorarium 50 guineas.

HOSPITAL FOR WOMEN, Soho-square, W.—Honorary Assistant Anæsthetist. Also House Physician for six months. Salary £30.

HULME DISPENSARY, Manchester.—Honorary Physician.

INDIAN MEDICAL SERVICE, India Office, S.W.—Nineteen appointments in Indian Medical Service.

LIVERPOOL BOROUGH HOSPITAL, Bootle.—Junior House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House Surgeon for six months. Salary £25, with board and lodging.

LONDON HOSPITAL, Whitechapel, E.—Surgeon.

LONDON TEMPERANCE HOSPITAL, N.W.—Assistant Resident Medical Officer for six months. Honorarium at rate of 50 guineas per annum, with board, residence, and washing.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Non-resident House Surgeon. Honorarium at rate of £25 per annum.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Assistant Physician.

NORFOLK AND NORWICH HOSPITAL.—Second Assistant House Surgeon for six months, with board, lodging, and washing. Honorarium £20.

NORTHAMPTON GENERAL INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, attendance, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, light, and fuel.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Resident Medical Officer. Salary £150 per annum, with apartments, attendance, coal, and light.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, Plaistow, E.—Resident Medical Officer. Salary £100 per annum. Also Assistant Resident Medical Officer. Salary £80 per annum. Both with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Honorary Dental Officer.

SOMERSET AND BATH ASYLUM, Cotford, Taunton.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, and washing.

STAFFORDSHIRE COUNTY ASYLUM, Stafford.—Junior Assistant Medical Officer, unmarried. Salary £150, rising to £200, with apartments, board, &c.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

SUSSEX COUNTY HOSPITAL.—Second House Surgeon and Anæsthetist.

SWANSEA GENERAL AND EYE HOSPITAL.—Resident Medical Officer. Salary £75, with board, apartments, washing, and attendance.

THROAT HOSPITAL, Golden-square, W.—Junior House Surgeon. Salary £100 per annum, with lunch.

WHITTINGHAM COUNTY ASYLUM, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary £150, with apartments, board, washing, and attendance.

WILTS COUNTY ASYLUM, Devizes.—Assistant Medical Officer, unmarried. Salary £160 a year, rising to £190, with board, residence, attendance, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Physician. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory Acts at Rochford in the county of Essex.

Births, Marriages, and Deaths.

BIRTHS.

ALDERSON.—On May 16th, at Eldon-square, Newcastle-on-Tyne, the wife of Wilfred B. Alderson, M.D., M.S. Durh., of a son.

BOW.—On May 20th, at Pentland-terrace, Edinburgh, the wife of M. Ranken Bow, M.B., C.M. Edin., of a daughter.

MAUND.—On May 17th, at Brackley House, Newmarket, the wife of John H. Maund, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

GOODMAN—CLAY.—On April 28th, Cyril Goodman, M.A., M.B. Cantab., of Cairo, to Sue Elizabeth, younger daughter of Cassius M. Clay.

STANDAGE—LONSDALE.—On March 11th, at Holy Trinity Church, Bangalore, India, by the Rev. A. J. Jones, M.A., chaplain, Captain Robert Fraser Standage, I.M.S., son of the late Alfred Standage, of Hurcott, Worcestershire, to Gwendolen, daughter of the late William Lonsdale of Hutton Roof, Eastbourne.

SWINDALE—NEALE.—On May 19th, John Aston Swindale, M.B., B.S. Durh., to Mary Frances, daughter of W. A. Neale, J.P., of Waihi, N.Z.

DEATHS.

BODINGTON.—On May 8th, in Paris, George Fowler Bodington, M.D. Durham, F.R.C.S. Eng., M.R.C.P., late Superintendent of the Government Asylum, British Columbia, aged 73.

SIMMONDS.—On May 24th, at Camberwell-road, Henry Morris Simmonds, M.R.C.P., L.S.A., aged 75 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

FEES FOR INSURANCE EXAMINATIONS.

WE have received several more communications concerning the fees tendered by life assurance societies to medical men for undertaking the examination of candidates for policies. One of them contains the form of the medical report required by the Gresham Life Assurance Society, Limited. The report is marked "North-eastern branch, Parade Chambers, High-street, Sheffield; Francis Rankine, District Manager," so that perhaps it is not in general use by the society. It consists of questions to be put by the medical examiner to the person whose life is proposed for assurance and it is suggested that the medical man should take down the answers of the person examined, as far as possible, in his own words. The medical man is first asked to fill up a long tabular statement regarding the family record, spaces being left for such useful information as the existence of the candidate's sister's gout and the duration of his or her mother's father's last illness. Then follows a table under six main headings with 28 sub-headings, setting out the applicant's pathological history. We pity the medical man who has to fill up such a table and the applicant who has to answer the questions. Then we come to the medical examination. Four observations are required about the heart and five about the chest, elaborate measurements being necessary for conscientious answers. Five observations have to be made about the urine—and it is not considered sufficient that a medical man should state the presence or absence of albumin or sugar; he is also asked to state the tests which he has employed. We note that the medical man is constituted a kind of detective in behalf of the Gresham Life Assurance Society, Limited. He is asked how he has identified the person proposing to assure as himself or herself, and whether the sum proposed is excessive in relation to his or her position in life. Altogether it is preposterous that a medical man should be asked to undertake the filling up of such a document; but if he is seriously asked to render such service to the society he should be paid properly and not be offered 10s. 6d.

THE R.A.M.C. UNIFORM.

To the Editors of THE LANCET.

SIRS,—I am much obliged to "V. M. O." for his letter which appeared in THE LANCET of May 17th, p. 1440. In reply to "Surgeon Lieutenant-Colonel" I beg to say that some little time ago I received a memo from the Volunteer Ambulance School of Instruction to the effect that Volunteer medical officers were to wear "Sam Browne" belts of R.A.M.C. pattern in all orders of dress except review order, &c., and in Paragraph 240 of the Volunteer Surgeon's Guide these instructions appear.

I am, Sirs, yours faithfully,
SURGEON-CAPTAIN.
May 24th, 1902.

A PLEA FOR THE FINAL YEAR STUDENT.

To the Editors of THE LANCET.

SIRS,—In these days of cramming and multitudinous subdivisions of subjects for the last and qualifying tests of our examining boards, the lot or burden of the poor student is becoming unbearable. After some years of a busy working-class practice in a large manufacturing city I am forced to admit that with a few exceptions I derived very little material benefit from the questions put to me at my "final." To prepare the general practitioner who constitutes about 85 per cent. of all medical men turned out each year, for his future career there are practically seven or eight absolutely essential subjects which he should be well and practically taught—namely, anatomy, physiology, materia medica, surgery, medicine, midwifery, forensic medicine, and chemistry; the remaining few odd subjects, which have been added during the past few years, are pharmacy, biology, and pathology including bacteriology. I shall begin with pharmacy. Beyond what can be learned in a couple of hours about this subject in these days of manufacturing chemists nothing is practically left for a medical man to do in the way of dispensing. As for biology, what examples of this science present themselves to the busy practitioner? None, so far as my experience goes. Lastly, there come pathology and bacteriology. Would it not be quite sufficient for the present-day student to be taught and examined in the grosser pathology which is encountered in general medical and surgical practice and in which the students of 10 and 15 years ago were well versed and in my opinion were, and are up to the present time, as good and as practical men as are now being turned out? What have the researches of bacteriologists done to shorten the course and duration of diseases supposed to be of microbic origin? Phthisis still is rampant and still incurable. Enteric fever runs its full course and still presents its complications. Of what use is the knowledge of a microbe to the practitioner when called out between 1 and 2 o'clock on a winter's morning to the bedside of a man stricken down with pneumonia? Is not a knowledge of what will relieve and soothe his patient to be much preferred?

Since the introduction of bacteriology and antiseptics the poor student is having a hard time and he gets these two subjects so deeply ground into him that for the first six months or so of post graduate life, when launched into a busy practice, he goes forth with fear and trembling, and at night may possibly suffer some remorse lest he has omitted some part of professional technique. After that time he begins to acquire more confidence in himself, forgets, fortunately for himself, a large number of theories, and then his success commences. In conclusion, on behalf of the large number of future general practitioners I would like to suggest that examining boards should include men recruited from the ranks of the busy general practitioner class—men of not less than 20 years' experience—as they are well fitted to know exactly what is required of the student, being themselves so much in touch with the sick and suffering. Each student should also be allowed to perform under personal supervision the minor operations of the surgical and obstetrical arts, such as minor amputations, circumcision, putting on forceps, and the administration of anæsthetics, thereby making him self-reliant and skilful. It is not possible for everyone to attend post-graduate schools.

I am, Sirs, yours faithfully,

Belfast, May 14th, 1902. R. H. D. POPE, L.R.C.S. Irel., &c.

MEDICAL MAGISTRATES.

THERE is no doubt that medical men as magistrates could summarily dispose of many cases of malingering and of pretenders who claim to have received bodily injury. As an instance of this a tramp at Scarborough, on May 27th, claimed exemption from work in the workhouse alleging that he had a broken arm. The arm was examined by one of the magistrates who happened to be a qualified medical man. The limb proved to be merely bruised and not broken. The magistrates sentenced him to 14 days' imprisonment.

THE "Y" FUND.

SURGEON-GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Professor and Mrs. A. E. Wright, Staff Surgeon J. H. Thomas, R.N., "F. E.," Dr. E. Baxter Forman, Dr. Kerr, Dr. Fuller England, Dr. R. C. Brown (Preston), Mr. J. R. Preston (Fleetwood), "A Well-Wisher" (through Mrs. C. White), Mrs. Dallas Edge, Mrs. J. Irwin, Mrs. H. Stokes, Surgeon-General A. F. Preston, A.M.S., Surgeon-Colonel W. T. Martin, A.M.S. (retired), and the following officers of the Royal Army Medical Corps: Lieutenant-Colonels E. M. Wilson, C.M.G., D.S.O., W. S. Pratt, W. G. A. Bedford, C.M.G., J. G. MacNeece, R. Vacy Ash, N. McCreery, G. T. Trewman, H. H. Stokes (retired); Majors W. H. Horrocks, E. R. Cree, H. P. G. Elkington, Birt, James, Captain J. Clarke (M.); and Lieutenants A. F. Carlyon and W. M. Power. The fund now amounts to £198. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens-terrace, Hyde Park, London, W.

NOTIFICATION OF DISEASE.

To the Editors of THE LANCET.

SIRS,—May I call attention to one objection there is to the compulsory notification of disease by medical men as it is now in vogue? In poor neighbourhoods the visits and attendances of medical men have to be cut down to the lowest actually necessary amount. Many of the notifiable complaints are difficult to identify without proper observation—in some cases lasting for days. Medical men practising in poor neighbourhoods know that they may only have one chance of seeing patients who come or are brought to the surgery. They know also that their visits to the homes of the patients must either be gratuitous or unwelcome to the patients and their friends. But if, in face of these facts, a medical man seeing a suspicious case—scarlet fever, typhoid fever, or small-pox—and preferring to avoid risk of infection and spread of the disease certifies "that *in my opinion* the person, &c.," is suffering from one or the other of these diseases he may find that the patient's friends after a day or so receive a note from the medical man at the hospital to the effect that it "does not appear that so-and-so has been suffering from such and such disease." And so the medical man is discredited and loses patients because another medical man says that his opinion is different. For with the poor "hospital doctors" and "hospital opinions" cannot err—"can do no wrong." This is particularly the case when the hospital is unknown or at a distance. *Omne ignotum pro terribile.* Of course, it is just possible that after all the original medical attendant may have been right. Undoubtedly, the mistakes that have been detected in notifications of these diseases do in many cases arise from this cause. Therefore, a medical man must ask himself, "Shall I notify or shall I let the infection take its chance?" For my part, having some regard to the good opinion of the people among whom I am practising, I have come to the conclusion that it is wiser not to notify until you are quite sure. But then while I am making sure I am perhaps spreading the disease. The truth is, it is not fair to put medical men in this dilemma. If there is found to be an error or a difference of opinion about the case after further observation at the hospital it ought to be the notifying medical man who receives the information and silence ought to be observed both to the patient and to the friends. As it is at present the patient or the friends are practically told that "their fool of a doctor has made a mistake," with the inevitable consequence to the doctor. It may be said that there is always the medical officer of health to be called upon as a second opinion. But this is not the case. Medical men have no hold upon the casual cases brought to their surgeries. If people have any suspicion they will give false addresses sooner than be notified as infectious.

Nor is this all. I was called to a case which I was able to watch. I identified it after a day or two as chicken-pox, but knowing the possibility of human error I decided to call the medical officer in to see the case. He came and declined to say on first visit. He came again and certified the case as small-pox. The patient was taken to the hospital. Next day an intimation was received by the friends from the hospital that the case was one of chicken-pox. Then I scored, but the remarks about the medical officer of health for the district were the reverse of complimentary for all that I could do to explain the difficulty. For obvious reasons I must not publish my name, but I inclose a card and sign myself THE MISUNDERSTOOD.

May 20th, 1902.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

Additional subscriptions:—Lieutenant Langford Lloyd, 10*s.*; Major F. Smith, 5*s.*; Captain G. A. T. Bray, 10*s.*; previously acknowledged, £89 10*s.*; Total, £90 15*s.*

LAPSUS LINGUÆ.

A COMICAL incident occurred in the Plymouth Police-court on May 21st. A considerable number of parents were summoned for neglecting to have their children vaccinated and much amusement was caused when, in one of the first cases, the presiding magistrate gravely announced that an order would be made for the child to be "baptised" within 14 days. Apparently the magistrate could not get the phrase out of his mind, for he erred in a precisely similar way three times within an hour.

◆

Mr. A. Robinson and Mr. L. J. Serin.—Before we can publish comments on the practice of selling drugged and fermented milk as nursery milk we must have proof of its existence. We shall be happy to receive any literature on the subject and any references to the conviction of offenders.

L. P. G.—Undoubtedly the General Medical Council might take notice of such conduct but the information must be properly laid before them. They cannot be expected to pay attention to anonymous accusations.

A. S A. may possibly find the information that he seeks in our advertisement columns. He should communicate with the secretaries or superintendents of the various nursing associations.

Entomologist.—D. Sharp's "Insects" (Cambridge Natural History Series), published by Messrs. Macmillan and Co., contains all the information and more.

M.B., F.R.C.S.—With certain precautions which the makers enjoin the "Pasteur" filter would fulfil our correspondent's requirements.

M.B., B.C., is recommended inaction. Why stir up a dead quarrel?

Ishmael.—The references will be found in Neale's Digest.

During the week marked copies of the following newspapers have been received:—*Hong-Kong Daily Press, South-Western Star (London), Western Daily Mercury, Yorkshire Mercury, Cork Constitution, Sheffield Independent, Bradford Observer, Morning Post, Essex Herald, Hereford Mercury, Hartlepool Mail, Suffolk Chronicle, Surrey Advertiser, Bristol Mercury, Dublin Express, Darlington Star, Times of India, Daily Graphic, Huddersfield Examiner, Sanitary Record, Local Government Chronicle, Hertfordshire Mercury, Dundee Advertiser, West Sussex Gazette, Bolton Chronicle, Kent Messenger, Middlesbrough Gazette, Birmingham Post, Rushden Argus, &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), *Gt. Northern Central* (2.30 P.M.) *West London* (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.).

TUESDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

WEDNESDAY (4th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

THURSDAY (5th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West *London* (2 P.M.), *Chelsea* (2 P.M.), *Gt. Northern Central* (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.) St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

SATURDAY (7th).—Royal *Free* (9 A.M.), *London* (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.) Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.).

At the *Royal Eye Hospital* (2 P.M.), the *Royal London* Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (4th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by *Dr. Lewers*, *Dr. A. Lea*, and *Dr. Williamson*. *Mr. M. Robson*: *Notes* of a Case of Primary Ovarian Gestation (showing the specimen). Paper:—Mr. A. Doran: Pregnancy after Removal of both Ovaries for Cystic Tumour.

THURSDAY (5th).—RÖNTGEN SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—The President: The Sources of Phosphorescence.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 P.M. Clinical Cases will be shown.

FRIDAY (6th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (Society's Rooms, West London Hospital).—9 P.M. Cases:—Dr S. Taylor: A Case of Symmetrical Œdema of the Legs in a Man.—Dr. A. Saunders: Rheumatic Endocarditis in a Case of Transposed Viscera.—Dr Beddard: Pulmonary Stenosis.—Dr. A. Saunders: Pulmonary Stenosis.—Dr. G. P. Shuter: A Case of Acromegaly.—Mr. J. R. Lunn: (1) A Case of Doubtful Congenital Dislocation of Hip in a Girl, with Skiagram; *(2) A Case of Arteritis of the large Vessels* with no Pulses at the Wrists in a Man; (3) Epithelioma of the Finger of a Man, with Sections for Microscope.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (2nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Ball: Discharges from the *Ear, their Causes and Treatment.*

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr J. J. Pringle: Clinique. (Skin.)

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

TUESDAY (3rd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Malignant Diseases of the Uterus.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. James Taylor: Clinique. (Medical.)

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. K. Pearson: The Laws of Heredity with Special Reference to Man.

POST GRADUATE CLINICAL DEMONSTRATION (Westminster Hospital).—4.30 P.M. Dr. W. A. Wills: A Case of Raynaud's Disease with Sclerodermia (with some other illustrative cases).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Ferrier: Disseminated Sclerosis.

WEDNESDAY (4th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. McAdam Eccles: Surgical Anatomy.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Jackson Clarke: Clinique. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Habershon: Congenital Heart Disease.

THURSDAY (5th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Medical Anatomy and Physical Diagnosis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr Hutchinson: Clinique. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Voelcker: Demonstration of Selected Cases.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Galloway: Demonstration of Dermatological Cases. (Post-Graduate Course.)

FRIDAY (6th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr Reece: Small pox and Vaccination.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. Jobson Horne: Clinique. (Throat.)

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Sir B. Baker: The Nile Reservoir and Dams.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. F. Alcan, Paris; Mr. E. P. Ashmore, Lond.; Mr. V. E. R. Ardagh, South Shields; Professor J. G. Adami, Montreal; Dr. David M. Aitken, Lond.; Messrs. Ayrton and Saunders, Liverpool; A. L. M.; Messrs. Albery and Lawrence, Hove; Mr. W. Alabaster, Lond.

Notes, Short Comments, and Answers to Correspondents.

SCOTTISH POOR-LAW MEDICAL OFFICERS.

THE dispute about the parish of Clyne Poor-law medical officer still continues. A special meeting of the parish council was held on March 25th, at which a letter from the Local Government Board for Scotland was read wherein it was pointed out that a parish council has no concern with its medical officer except in so far as he is medical officer to the paupers under care of the guardians. The parish council, however, could give its medical officer due notice to go at the end of his year of office, and it need not assign any reason for so doing. It was mentioned at the council that a plébiscite of the ratepayers had been taken on the question. The votes were as follows In favour of Dr. G. Nicoll remaining, 200; against, 14; neutral, 32. Finally, a motion was carried by one vote saying that it was inadvisable for the parish council to interfere but that it was very desirable that Dr. Nicoll should be available as far as could reasonably be expected. The whole position is absurd and arises from the parish council going outside its province. It has a duty to provide medical attendance for paupers, but it is in no way its duty to provide a parochial medical attendant. If the inhabitants of Clyne wish for a medical man to reside in their midst to be entirely devoted to their service they should offer a suitable retaining fee, but even then we doubt whether any self respecting medical man would consent to put his liberty of action in the hands of such persons as some of the ratepayers of Clyne would appear to be from the published reports of their actions.

THE MEDICINAL PROPERTIES OF SAFFRON

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 15th, at page 469, there is a reference to saffron and its properties, in connexion with which the following notes may be of interest to readers of THE LANCET.

Sadīdu Kāzerūnī (circ. 1350 A.D.), in his commentary entitled "Al-Mughnī" (*liber sufficiens*), on the "Kānūn" of the famous Ibn Sīnā (Avicenna), writes as follows regarding saffron [illegible] wonderful effect in strengthening the mental faculties, [illegible] brilliance, and causes exhilaration and cheerfulness. Strong[illegible] perfumes are valuable adjuvants."

Again, the "Bahru-l-Jawāher" ("Ocean of Essences") states: "Saffron prevents the flow of moist humours to the eye when used either as an ointment or as a collyrium. It is hot in the third degree, dry in the first degree, laxative and digestive, improves the complexion, and when mixed with wine is very intoxicating, causing heaviness, headache, and drowsiness. It clears the eyesight, facilitates parturition, is a respiratory stimulant and cardiac tonic; is diuretic, controls the animal passions, is of service in internal pains and uterine disorders, dispels the effects of a debauch, is aphrodisiac, and beneficial in diseases of the spleen."

The "Makhzan-al-Adwiya" ("Storehouse of Medicaments") gives the following account of "the properties and actions of saffron." "Exhilarating and tonic to the five senses, excitant and digestive, laxative and corrective of the impure humours arising from the phlegm, preserving them from alteration and corruption. It is diuretic and astringent, aphrodisiac, and stimulant to the animal spirits, is a hepatic and intestinal tonic, and a respiratory stimulant. Its use provokes mirth and laughter, purifies the kidneys, bladder, and skin, and conveys the virtues of other drugs to the heart and all the viscera. It removes obstructions of the brain, liver, and spleen."

If saffron really possesses the qualities claimed for it by Oriental physicians and pharmacologists, we have at once a reason for its use in decoctum aloës compositum, and it is evident that its removal would be a loss.

In any case it is interesting to know that saffron has for more than five centuries possessed a high reputation for efficiency in the above-noted particulars. I am, Sirs, *yours faithfully*,

GEORGE RANKING, M.D. Cantab., Lieutenant Colonel I.M.S.

Calcutta, March 6th, 1902.

SADDLE SORENESS.

IN the April number of the *National Cyclists' Union Review* Mr. E. B. Turner, F.R.C S. Eng., discourses upon "Saddle Soreness, its Causes, Prevention, and Cure." There are plenty of causes but Mr. Turner is fain to confess that there is practically no prevention and no cure. A member of our staff says that from his own experience he can say the same thing. He has tried all sorts of saddles and has finally settled down to one which everyone whom he has asked to try it pronounces to be abominably uncomfortable. The only way to avoid saddle soreness is for the rider to make trials of saddles until he finds one that he likes and has got it properly adjusted. When this desirable consummation has been achieved let him on no account move the saddle. Let him remember, too, that, as Mr. Turner points out, a bicycle must be ridden and not simply sat upon, and he should also remember that no one saddle will fit everyone any more than will a boat, or a gun, or a pair of boots.

INCONTINENCE OF URINE.

To the Editors of THE LANCET.

SIRS,—I shall be glad if anyone who has had successful experience in the treatment of the incontinence of children will inform one of his less fortunate brethren as to the remedies employed. In a case which I have had under my care for a considerable period none of the usual drugs have had any permanent effect. I have tried gradually increasing doses of tincture of belladonna, both alone and in combination with liquor strychninæ but with only temporary relief. As soon as the higher doses are withdrawn the habit returns. As the boy in question is located at a big public school it is, of course, a great drawback to him. I may say that the urine is normal as to reaction and specific gravity. Any hints as to treatment will be gratefully appreciated.

I am, Sirs, yours faithfully,

April 1st, 1902. S. S. B.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

WE received on April 1st, from Major B. M. Skinner, R.A.M.C., the secretary to the fund for the memorial to Surgeon-General W. Nash, A.M.S., the following list of further subscriptions:—

	£	s.	d.
Surgeon-General J. A. Marston, C.B., K.H.S.	1	1	0
Colonel G. Leake	1	1	0
Colonel H. Comerford ...	1	1	0
Lieutenant-Colonel B. McCreery	0	10	0
Lieutenant Colonel Odo Cross	1	1	0
Surgeon-General J. L. Jameson	2	2	0
Colonel F. B. Scott, C.M.G.	1	1	0
Colonel W. McWatters ...	1	0	0
Major G. E. Moffet.. .	0	10	0
Surgeon-General J. Jameson, C.B.	1	1	0
Lieutenant-Colonel W. Johnston	1	1	0
Major S. G. Allen	0	5	0
Previously acknowledged in THE LANCET of March 15th (p. 764) and 29th (p. 919)	23	2	0
	£34	16	0

Subscriptions promised should be remitted as stated in THE LANCET of March 15th, p 764. They will be duly acknowledged.

R. M.—The position of public vaccinators is a very difficult one. Our correspondent will find the matter discussed in an article in THE LANCET of Nov. 16th, 1901, p. 1352. We do not wish to say anything that might check the very necessary wholesale vaccination that is now taking place, though we are quite aware that the methods of some public vaccinators are open to question.

Colonist.—The M.D. Brux. is registrable in Australia and the regulations of the universities there, according to the Australian Medical Directory, make allowances in many cases for work done elsewhere.

A Subscriber for the Last 30 Years.—The matter is one for arrangement The incomer should receive only his share of the money earned since the date of partnership.

R. W. E.'s verses are to the point, but the subject is just now so fraught with serious issues that we think it well not to deal lightly with it.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, April 3rd, 1902

During the week marked copies of the following newspapers have been received:—*Greenock Herald, Wyndham Farmer (Otago, N.Z.), Redditch Indicator, Surrey Advertiser, Coventry Herald, Belfast News, Birmingham Daily Mail, Municipal Reformer, Echo, Standard, Bristol Mercury, Liverpool Daily Post, Herts Advertiser, Times of India, Reading Mercury, Mining Journal, Local Government Chronicle, Hertfordshire Mercury, Windsor and Eton Express, Portadown News, Sunday Magazine, Kensington News, Daily Telegraph, St. James's Gazette, Pharmaceutical Journal, Manchester Guardian, Dublin Evening Telegraph, Gazette Méd Paris, &c.*

The Lettsomian Lectures

ON

CERTAIN DISEASES OF THE BLOOD-VESSELS.

Delivered before the Medical Society of London

BY A. PEARCE GOULD, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE III.[1]

Delivered on March 17th.

MR. PRESIDENT AND GENTLEMEN,—The very interesting problems connected with the occurrence of thrombosis and the great practical importance of the affection are, I hope, a sufficient justification for my devoting this lecture to that subject. Ever since the science of physiology has existed the coagulation of the blood has been a phenomenon of absorbing interest to physiologists, and although many keen observers and profound thinkers have devoted much patient labour to its study we have to confess that it remains to-day in great measure an unsolved mystery. But if the coagulation of the blood is one of the great elemental problems to the physiologist, thrombosis, or the coagulation of the blood in living blood-vessels, is a theme of equal interest and importance to the pathologist and to the practitioner of medicine and surgery. To its beneficent agency we owe the very existence of our race. The great function of reproduction seems to be specially dependent upon the benign influence of thrombosis in sealing the tiny vessels in the ovary when an ovum bursts from the Graafian follicle, in closing the ruptured vessels of the torn hymen, and in plugging the much larger uterine sinuses which are opened by the separation of the placenta. The whole art of surgery may without any exaggeration be said to have been possible only because blood may coagulate within living vessels and the debt of surgery is perhaps only fully realised when one stands almost impotent beside the ceaseless dripping from a wound in a hæmophilic patient. For most of us, I fear, the word "thrombosis" conjures up before our minds not these benign effects but some of those disastrous results which we so often see following upon the untimely clotting of blood within the vessels. We think of pains and long-drawn-out disabilities, of extended periods of rest and idleness, perhaps of permanent lameness or paralysis, or even of sudden death, or the ante-mortem agony, all of them so often resulting from thrombosis. Indeed, it plays almost as prominent a part in disease and death as in the preservation of health and life; perhaps we hardly realise how large a part it plays and it is not uninstructive to use some spare moment by trying to count up the many and different forms in which we meet with thrombosis and how enormous an advance in practical medicine it will be when thrombosis will be known only as a beneficent phenomenon and when we are able to prevent its occurrence as a baneful process. As a very minor illustration of the importance of thrombosis and of the large influence it may have in marring a life I may mention a case I saw last year of a man, 49 years of age. He told me that in 1876 he was attacked with typhoid fever and during his convalescence he suffered from thrombosis of first one femoral vein and then the other, for this he was laid aside for 18 months. Ever since that time he has been liable to thrombosis from slight injuries and, indeed, it has often occurred without obvious exciting cause, and out of 25 years he has spent no less than six years, two months, and one week invalided by these successive clottings! When I saw him last July he had plugging of the left median basilic and the lowest inch of the basilic vein, which had quickly followed upon his being rather roughly seized by the left elbow. I feel sure that all of you can recall case after case where blood-clotting has proved almost as great a bar to a happy, useful, vigorous life as in this case. I forbear to speak of those many tragedies that we witness as the result of the sudden detachment of one of these clots.

It is no wonder, then, that the literature of thrombosis is very extensive and that many of the greatest pathologists—John Hunter, Cruveilhier, Virchow, Paget, Lister, Cohnheim, and a whole host of others—have made it a special study and have endeavoured to fathom the deep mystery that covers the origin and nature of intravascular coagulation. I cannot attempt to sketch the history of the theory of thrombosis, how it has gradually been freed from error and misconception and amplified by new facts. I propose only to touch upon a few points and to mention one or two of the less commonly seen forms of thrombosis that have happened to come under my observation.

The first appearance observed in circulating blood about to clot is the presence of minute protoplasmic masses called "platelets" which becoming increasingly viscous cohere into tiny irregular masses. These platelets are probably not constituents of normal circulating blood, but are derived from the red corpuscles, possibly from their disintegration. Their increasing viscosity is probably dependent upon some unknown condition of the blood plasma. Around these minute masses of agglutinated platelets fibrin is deposited and incloses corpuscles in its meshes if the blood-stream is not so turbulent as to "whip" them out of the forming fibrin. This fibrin is deposited from the blood in such a way as to impart to the clot a definite structure. But the question that interests us most is, Why do these clots form? What is the condition antecedent to the formation and agglutination of the platelets? Is it to be sought in the blood or in the blood-vessel? These are questions as old as the scientific study of pathology and a full and completely satisfactory answer to them is not yet forthcoming. John Hunter regarded a plastic inflammation of the vessel wall as the primary and essential step in the whole process and Cruveilhier advocated the same view. Virchow in his great work on thrombosis and embolism laid stress on the opposing view and regarded the coagulation as a blood change effected by some alteration in the blood itself independent of changes in the vessel-wall, which, however, were often set up by the presence of a blood-clot. More lately, and as the outcome of the study of micro-organisms and the part they play in so many forms of disease, it has been shown that in many thrombosed vessels bacteria are present both in the vessel-wall and in the clot, and it is thought that these organisms may be the primary cause of the coagulation. Opinions differ, however, as to whether the micro-organisms produce the clotting by acting directly upon the blood-cells or whether by their presence in the vessel-wall they set up changes which unfit them for their special function of maintaining an open channel for the blood and thus lead to blood coagulation. It is evident that if a blood change is the chief cause of intravascular coagulation there must also be some local condition that determines the thrombosis at a particular part of the system. This is a problem of exactly the same kind as that presented by other local manifestations of general infections, such, for example, as acute infective osteo-myelitis, tuberculous and syphilitic osteitis. In each case there is a general infection and a localising influence.

As regards the blood itself, we must abandon the idea that a condition of hyperinosis—an excess of fibrin—ever plays any part in the causation of thrombosis. The proportion of fibrin present in the circulating fluid no doubt varies within somewhat wide limits, but the greater or less tendency to thrombosis never depends upon the more or less of fibrin present, but upon some agent that excites the separation of the fibrin from the plasma. The blood changes that might bring about thrombosis we may suppose to be one or more of the following: (1) a change in the corpuscles leading to their disintegration; (3) an increase in the viscosity of the platelets; (3) an increase in the fibrin ferment; and (4) an increased liberation of fibrin ferment. It is possible that various micro-organisms or their toxins may influence in some way or other either the formation of platelets from red corpuscles or the production of fibrin ferment in the blood. It is also possible that certain products of inflammation absorbed into the general blood stream may have the same effect. Bearing upon this question is the well-known fact of the tendency of a clot once formed to extend—in the direction of the circulation, it is said. This growth of a clot is sometimes very rapid and very extensive and one explanation of it is that there escapes from the clot first formed some element capable of exciting coagulation in the adjacent blood, fibrin ferment possibly. If this is so it affords support to the view that a blood change may be both the primary step in thrombosis and the direct cause of the coagulation. Conversely, it has been shown that a state of the blood may be induced in which coagulation cannot occur, and it is thought that an exhaustion of fibrin ferment may actually be the nature of this change. The late Sir William Roberts suggested that gouty thrombosis might be due to the presence in the circulating blood of minute particles of uric acid which he thought might have the same effect in exciting coagulation as the addition of minute crystals or other fine particles to recently shed blood.

---

[1] Lectures I. and II. were published in THE LANCET of March 1st (p. 576) and 15th (p. 717), 1902, respectively.

Thrombosis is so commonly a localised affection that we are forced to consider the local conditions which influence it as of primary importance. They may, so far as we know, be grouped under two heads—(1) changes in the nutritive condition of the vessel walls and (2) changes in the regular equable flow of the blood. The changes in the vessel wall include all traumatic, inflammatory, and degenerative changes—however produced—and, of course, include the consequences of the invasion of the tissues by streptococci and other micro-organisms. It is when these changes affect the integrity of the inner coat and particularly its endothelial lining that coagulation is most prone to occur. I referred to this point in my last lecture, and we saw in the disease we were then considering—arteritis obliterans—a striking example of the influence of disease of the tunica intima in causing clotting. Atheroma, calcification of the middle coat of an artery when so advanced as to interfere with the nutrition of the internal coat, acute infections of vessels either from without or from the blood within them, and all forms of injury are frequent causes of thrombosis and in many instances appear to be the sole causes acting independently of any special blood condition. However, we must not too readily conclude that a clot within a diseased vessel is caused entirely by that disease. In some cases an alteration in the blood is probably a contributory cause. The disease in the vessel is often very chronic and coagulation may be the result of ill-understood cumulative conditions. The full vitality of the blood is only maintained when the circulation is vigorous and all the great functions are regularly discharged. Diseases of blood-vessels are so very often associated with imperfections in the circulation and with defects in one or other of the great viscera that it must be that some change is often present in the blood flowing through these diseased vessels—a change predisposing it, perhaps, to develop platelets or to coagulate.

The circulatory disturbances which are believed to play an important part are those which result from (1) the sudden dilatation of a vessel, as one often sees in varix or aneurysm, or (2) the entrance of a small vein into a large one, or (3) the little pouchings naturally present in veins behind their valves. It is thought that in these situations slight irregularities of the flow of blood, little eddies perhaps, may occur—what Recklinghausen has called "Wirbelbewegungen"—and that here blood corpuscles break up into platelets and fibrin ferment is set free and clotting is started. In such a vein as the one I now hand round, where a dilatation of the size of a pullet's egg has developed in an internal saphenous vein which is not notably enlarged, we can understand that there must be a considerable departure from the regular even flow of blood in one direction—that is, the normal condition. Within this great sacculus clotting has occurred and it did not extend any distance beyond it. I excised this vein from the upper part of the leg of a woman and with an entirely satisfactory result. Cohnheim held that the full vitality of the endothelium of a vessel partly depended upon the regular and rapid flow of blood over it, and he suggested that in such cases as those which I have mentioned and in others of great enfeeblement of the circulation the natural stimulus—or whatever influence it may be—of this rapid steady blood-flow is lost, that as a result the endothelium suffers, and that from this follows some deteriorating effect upon the blood leading to its coagulation. This view is interesting as emphasising the great mutual influence and dependence of blood and blood-vessel.

There are two modifications of the circulation that I would like to draw special attention to. The first is the regurgitation from deep into superficial veins that is such a frequent, if, indeed, it is not an entirely constant, phenomenon in varicose veins. In the first of these lectures I described this phenomenon and mentioned how constant I had found it. I believe that the disturbance in the circulation it causes, the undue tension in the varices, is an important cause of thrombosis in varicose veins: I make this statement the more confidently because when I have operated in such a manner as to prevent this regurgitation (Trendelenburg's operation) I have found the tendency to thrombosis removed. I mentioned striking cases of this in my first lecture. I must not recapitulate them. There is no doubt that thrombosis is much more common in varicose veins than in others. Of course, several other explanations of this fact are forthcoming, such as the effect of the abrupt dilatation and pouching that I have already referred to, the projection of the veins exposing them to contusions and other injuries, and the degenerations or inflammations of the inner coat which occur more often in varicose than in healthy veins. But the good effects of occlusion of the highest part of the superficial vein affected seems to me to be strong evidence that the greater tension and the modification in the blood-current caused by reflux, must play an important part in leading to thrombosis. There is another well-known fact that bears upon this. I am sure that all of us have seen cases of thrombosis that we have treated *secundum artem* by rest in the horizontal position; we have been pleased to watch the arrest of the disease, the gradual lessening of the pain and swelling, and the passing away of all the unpleasant symptoms. At length the time has come when we have felt that the thrombus must be so far organised as to be firmly incorporated with the vessel wall and that the danger of embolism is past. We allow our patient to get up; the legs that have been horizontal for some weeks with low tension in all the vessels are suddenly put in the vertical position and the tension in all the vessels is raised. At once a fresh attack of thrombosis occurs. Why? From the injurious effect of an abrupt alteration (increase) of the tension in the veins. I have seen cases where this unfortunate accident has occurred time after time until many months have been spent by the patient in resting for one after another of his attacks of thrombosis. But this clinical observation is such a commonplace one that I need not detail cases to illustrate it. We all of us, I suppose, regard the period of first getting up as one full of risk for a patient with thrombosis, so frequently is it followed by a fresh clot. Negative evidence to the same effect is afforded by the good effect upon thrombosis of rest in the horizontal position. How commonly it is attended with immediate arrest of extension of the clot and of all the other symptoms. It is the lessened tension in the veins that is the chief cause, I submit, of the improvement. And here I may mention one other point. We all know that thrombosis is much more common in the lower limbs than in the upper. Why is this? Is it not mainly because the tension in the veins undergoes greater, more frequent, and more prolonged increase in the lower limbs than in the upper? The general higher vitality of the upper than the lower limbs, which is shown in so many ways, may also partly explain this difference. A striking confirmation of this view is afforded by the fact that venous thrombosis occurs more often from tricuspid regurgitation than from any other form of heart disease.

The other alteration in the circulation that I wish to refer to is that produced by a block in a main artery. It is commonly stated that when a clot forms in a vessel it exhibits a tendency to extend in the direction of the circulation. This is undoubtedly true of venous thrombi but it is not true to the same extent of arterial thrombi. Here we often see that the thrombus extends up along the artery towards the heart and it may be for some distance. I may remind you of some of the cases of obliterative arteritis I mentioned in the last lecture in which, for instance, the arterial disease with occlusion by clot extended as far as up to the popliteal artery, but the thrombus extended not only the whole length of the femoral artery but in one case the clot reached up to the aorta and even as high as the origin of the renal artery. I think it is truer to say that both in arteries and veins clots tend to grow centrally and towards the heart.

Another very important modification of the circulation is that brought about by great enfeeblement of the heart. Thrombosis undoubtedly occurs in many conditions of enfeebled circulation and Virchow especially has described these so-called marantic thrombi. But not only is there no exact relationship between the rate of blood-flow and coagulation, but recent observations have demonstrated the presence of micro-organisms in many so-called marantic thrombi and this discovery necessitates a careful reconsideration of our theories of intravascular coagulation from mere slowing of the blood-stream. Micro-organisms have been demonstrated in thrombi in many conditions, such as puerperal thrombosis, post-enteric, post-pneumonic thrombosis, and in the clots occurring in the late stages of tuberculous disease, as well, of course, as in the more definitely septic conditions. The *organisms most commonly present in such* clots are streptococci staphylococci (less often), and occasionally the bacillus coli, bacillus proteus vulgaris, and some others. Only last year Dr J H. Bryant read a paper at a *meeting of the Pathological Society of London* in which he described four cases of thrombosis where he found organisms in the clots which he regarded as the cause of the coagulation, in one case he found streptococcus and staphylococcus albus, in two cases bacillus proteus vulgaris, and in one case the bacillus subtilis in one saphena vein, and staphylococcus in the opposite saphena vein, in each case in pure culture. A great deal of attention has recently been paid to this investigation, especially by French observers, and the belief is gaining ground that micro-organisms play a great and hitherto unexpected rôle in the pathology of thrombi. It may be so. But possibly we shall take a too narrow view if, because organisms are found in clots or on the walls of plugged vessels, we at once assume that the organisms are the sole or main causes of thrombosis, indeed, I would venture to suggest that the whole discussion of the causes of thrombosis, of which I have given a very imperfect outline, is vitiated by one fallacy The discussion is based on the assumption that a clear and sharp distinction is to be drawn between the blood and the blood vessels. Do we not press this distinction too far? Developmentally we know that they own one common source, in the mature state their inter relations are far more close than we readily imagine, and before we can truly appreciate the nature, causes, conditions of thrombosis I think we must grasp the idea that the blood and the inner coat of blood vessels are parts of one organ—of one organic whole. Any grave defect of this organ may lead to thrombosis and whether the change is initiated in the fluid blood or the more stable tunica intima is not a distinction of primary importance.

Leaving these more theoretical considerations I will ask your patience while I refer to one or two of the less common forms of thrombosis. I have seen at least two cases of thrombosis of the spermatic veins. One of the patients was a man, aged 32 years, under the care of my colleague, Mr G Lawson, at the Middlesex Hospital On Feb. 1st, 1894 he was kicked on the scrotum, a good deal of pain and swelling followed but he continued at his work as an asylum attendant that day Next day he stayed in bed and his pain was better He tried to get up on Feb. 3rd but finding his pain worse he went back to bed and stayed there till Feb. 7th and after that he did a part of his work each day till Feb 14th, when he was admitted to hospital because any strain or effort brought on an acute dragging pain in the left testicle. He was then found to have a firm, uneven swelling in the left cord in the upper part of the scrotum The *vas deferens* could be traced over its posterior aspect, not lost in the swelling and it seemed to be clear that this was a thrombosed spermatic vein. The patient was kept in hospital till March 5th, where he left convalescent. A year or two *before* this a youth, aged 18 years, was admitted to Middlesex Hospital under the care of Mr J W Hulke with a swelling in the left spermatic cord. He gave no history of injury and said that he had noticed a dragging pain in the part for three or four days. In this case a firm narrow cylindrical cord could be felt extending from the top of the left testicle up to the external abdominal ring It was clearly in the spermatic cord and quite distinct from the vas deferens, and Mr Hulke and others who saw it were quite clear in their opinion that it was a thrombus in a vein of the spermatic plexus The testicle was a little tender only There was no urethritis in either of these cases. This patient, like the other, was rested in bed and left the hospital convalescent.

My colleague Mr Henry Morris kindly allows me to mention a curious case that was under his care in the Middlesex Hospital. An unmarried woman, aged 28 years, accidentally noticed a lump of about the size of a pea in the left breast when she was feeling some pimples in the skin of the part. It gave her no trouble and she took no further notice of it. A year later, in May 1899 she bruised the left breast and two days after on feeling the painful part noticed a lump there which she thought was the same as the one noticed before. She was seen by one of the assistant surgeons to the hospital and advised to come in The note of her condition *on admission is as follows* "A tumour of small size is situated in the outer and upper segment of the left breast towards the axilla. It is about one inch long and half an inch across, placed radially from the nipple It is hard, smooth, somewhat lobulated, it is freely moveable. It does not fluctuate. It is felt to be in the mammary gland itself and to be over the pectoralis major The axillary glands are neither enlarged nor hard. A large abnormal vein runs across the left axilla—a congenital abnormality' Mr Morris operated and found the lump was a thrombosed vein in the breast. I think this must be a very rare experience and with such a history as this patient gave it would have been almost impossible to arrive at a correct diagnosis before the operation.

I have seen some cases of chronic spreading thrombosis which I think are probably closely allied to cases of arteritis obliterans and if I wanted to give a name to them I should call them *endophlebitis obliterans*. Up to the present I have only seen them in the superficial veins of the lower extremity The patient notices a little stiffness in the leg hardly amounting to pain and on feeling the part a slightly tender "knot" is felt. The symptoms at first are not severe enough to lead the patient to rest or to consult a medical man. Slowly the "knot" lengthens into a firm cylindrical cord which can be rolled under the skin or may be fixed to it by periphlebitic œdema—it is only a little tender to the touch. Steadily this induration of the vein—for such it is—extends up the leg and I have known it reach from the ankle to the groin. The connexion of the firm cord with a subcutaneous vein can easily be demonstrated. So far as I have seen the extension of the clotting and obliteration of the vein is always in an upward direction. I saw a case last year where a very robust healthy young married man, who had rather numerous but not very large varices scattered over the right leg and thigh was attacked with this form of thrombosis. When I saw him he had already been many weeks in bed and the clotting had been watched spreading up along the whole length of the internal saphena vein—quite up to the groin The treatment of these cases by rest is very unsatisfactory—it may entail several months of idleness. Excision of the thrombosed vein except at its earliest stage is a rather troublesome and wholly unnecessary procedure. I have found that to excise a portion of the vein a little above the evidently diseased part effectually stops the spread of the trouble. This is a very simple procedure and it has the further advantage that it removes the danger of embolism which might conceivably occur even in these cases of chronic thrombosis. Three years ago I had a woman under my care with this affection involving the left internal saphena vein up to a little above the knee. I removed an inch of the vein four inches higher up and in 14 days she left the hospital convalescent, the disease being arrested and the pain to which it had given rise had quite passed off.

Among the cases of obliterative arteritis that I related in my last lecture was one that I was indebted to the courtesy of Dr W Pasteur for the opportunity of seeing and for the permission to publish. In addition to the disease in the arteries of the legs which led to gangrene in the feet there were acute abdominal symptoms during the last few days of the man's life and it was to this abdominal condition that death was at last due The symptoms were persistent vomiting and the presence of an ill-defined tumour in the lower half of the abdomen—this was not resonant. The man died from exhaustion eight days after the onset of these symptoms. The necropsy revealed thrombosis of the superior mesenteric vein and partial obliteration of the companion artery, the mesentery and a certain length of the ileum were greatly thickened, hardened, and very dark in colour, being infiltrated with blood.

Thrombosis of the superior mesenteric vein is not a common condition Dr Welch has been able to find records of 32 cases, he states that the condition is commoner in the superior mesenteric vein than in the inferior and much more frequent in the mesenteric arteries than in the veins. I had an example of superior mesenteric vein thrombosis under my care two years ago and as the symptoms were exceedingly ambiguous I hope a brief summary of the case may be of interest. The patient was a carpenter, 40 years of age, who had enjoyed good health up to the time of the illness in question This illness began 12 days before he was admitted to the hospital with languor and a sense of fulness at the epigastrium His appetite was poor and he ate very little. Three days later (May 17th) his bowels ceased to act, no flatus even being passed. Four days later still (the 21st) he came to the hospital out-patient department complaining of loss of appetite and constipation; he had no pain, his temperature was normal, and his pulse was 88. He was ordered sulphate of magnesia and haustus gentianæ alkalinus. After three days more (the 24th) he was seized with severe pain at the epigastrium and for this he took next morning an ounce of castor oil which he retained but which did not produce any action of the bowels. Then on the 25th he began to vomit and he suffered much from paroxysms of griping pain at the epigastrium. On the 26th, as nothing had passed from the bowels for more than a week, his medical attendant administered a glycerine, and then a soap-and-water, enema which returned unaccompanied by any motion and he was then sent into the hospital. He was then, 12 days after the onset of the illness, a well-nourished man lying flat in bed with extended legs; he seemed to have no pain; his temperature was 98° F. and his pulse was 88; his tongue was thickly coated. His abdomen was not distended; it moved freely with respiration, its walls were flaccid; no peristalsis was visible. We could not detect any swelling or elicit any tenderness; the cæcum was not full. The liver edge was felt two inches below the costal margin at the end of inspiration; liver dulness was present. Elsewhere the abdomen was resonant There was no hernia; the rectum was empty and digital examination revealed no abnormality. The urine was acid, of specific gravity 1026, and loaded with urates; it was free from albumin and did not give the indican reaction. Soon after his admission an enema of castor oil was given, followed by soap-and-water; this was returned without any motion and soon afterwards he complained loudly of colicky pains and his pulse rose to 108 and became very feeble. Hot fomentations soothed him and in an hour his pulse was down to 80 and of good quality. The next morning (the 27th) Dr. Pasteur saw the man with me and we decided to give him calomel in one-grain doses every four hours till the bowels acted. After two doses he passed a slight motion of dark offensive liquid; he had great pain at the time and soon afterwards he vomited. But he had a comfortable night without pain and next day he took an ounce of compound senna mixture. On the 29th the bowels acted twice, the motions consisting of a small quantity of dark fluid with a little solid fæcal matter. There was now no vomiting, he was free from pain, and slept well; his pulse was 96. His abdomen was still quite soft and moved freely; there were a little tenderness and sense of resistance to the left of the umbilicus; he was passing flatus freely. But he did not have a good night and next day (May 30th) he complained of dull aching pains in both loins; there was no vomiting but also no motion; the abdomen was a little more distended, especially on the right side. At 3 P.M. he took half an ounce of castor oil and afterwards passed two motions, chiefly fluid. He vomited in the night and the acute pain returned. Dr. Kingston Fowler saw him with me on the next afternoon (May 31st) and agreed that there was no clear indication for immediate operation. We ordered morphia when the pain was severe. After this he became worse rather rapidly; the pain became very severe, vomiting returned, and his abdomen became distended and rigid and his pulse rose to 144. In my absence Mr. T. H. Kellock operated next morning, June 1st. He found a quantity of blood-stained serous fluid in the peritoneum, a long coil of the small intestine was of a dark-purple, almost black, colour, and the corresponding mesentery was thickened and firm with several hæmorrhages into it. Recognising that the condition was one not to be satisfactorily dealt with by operation Mr. Kellock at once closed the wound. The man died in the evening of the same day.

The following notes were taken at the necropsy. "Small intestine more or less gangrenous for entire length. Duodenum and upper one-third of jejunum were considerably discoloured and below this the walls were almost black. The intestine was neither distended nor collapsed. Coils slightly adherent through early inflammatory exudation. Large intestine and vermiform appendix normal. Mesentery greatly thickened, firm, and yellowish-green in colour Veins distended with blood-clot. Tissue round veins in portal fissure much thickened and the portal vein contained clot. The chief vein of pancreas was distended and filled with clot, which, however, appeared more recent than that in mesenteric veins. No definite changes in arteries. No constriction or any other lesion to account for gangrene. Pancreas appeared rather swollen, otherwise normal. Spleen enlarged and distinctly firmer than normal."

Mesenteric thrombosis seems to be most often caused by some intestinal lesion, but in my case none was observed. The symptoms usually set in abruptly with severe pain of a spasmodic colicky kind, referred to the epigastrium; vomiting quickly follows and the abdomen becomes distended and tender. There may be absolute constipation or there may be the passage of motions containing dark altered blood. Death appears to be an invariable result and surgery offers no succour to these patients. I must confess to being entirely nonplussed by the case which I have just related; in several particulars it differed from the common course of the affection, especially in its slow, gradual onset, the length of time which it lasted, and the periods of apparent improvement in all the symptoms.

The last cases of thrombosis to which I will refer are two occurring in the innominate veins. The first was in a little girl, 10 years old, a patient under the care of Dr. S. Coupland in the Middlesex Hospital in 1894. She was admitted on Dec. 18th suffering from typhoid fever. On Feb. 11th, 1895, when convalescence seemed to be progressing well, each external jugular vein was found to be thrombosed—firm, knotty, and exquisitely tender; on the left side the swelling around the vein became very marked. A week later, Feb. 19th, the note is: "Greatly improved. Feels well and is recovering strength rapidly. Neck is excessively painful still but the inflammation is certainly subsiding. Both external jugular veins are thrombosed. Temperature 100°." On Feb. 23rd she complained of pain in the chest below the right nipple. The superficial veins over the chest, especially on the right side, were enlarged, there was pitting on pressure on both sides of the chest, and the face looked puffy. There was no œdema of the upper limbs. There were no other physical signs of chest lesion. These symptoms continued and on Feb. 28th she had dysphagia. The œdema of the chest wall was greater: that of the face had disappeared. The neck was now less tender. The superficial veins over the chest were larger and appeared to be carrying on a collateral circulation. Then signs of fluid in the left pleura were detected and on March 8th she was tapped and 24 ounces of semi-purulent and sanguineous fluid were withdrawn; this seemed to give a certain amount of relief. But the child got worse. Thus on March 12th the note runs: "Child is generally worse; there is great puffiness of left side of face; great œdema of the chest wall. Pulse 136, very weak—indeed, scarcely to be felt at the wrist." The left pleura was again tapped on March 13th and this time one and a half pints of yellowish cloudy fluid were drawn off. Under the microscope a few pus cells were seen in it, together with a large number of red corpuscles in various stages of disintegration. During the tapping the aspirator unfortunately broke down twice and air was admitted to the pleura and to the subcutaneous tissue of the chest wall. Strange to say, two days later (March 15th) this child was sitting up in bed with a normal temperature and busy with her sewing. But the fluid reaccumulated and on March 17th I opened and drained the left pleura, evacuating two pints of thin pus. For a time respiration was terribly embarrassed and oxygen and brandy were administered; in an hour she became quiet, breathing well, and was evidently relieved by the operation. The patient then for a time steadily improved; her pulse became better and stronger and we began to entertain hopes of recovery. On April 12th a trace of albumin appeared in the urine; this rapidly increased in amount and by May 4th is noted as being present in "great quantity." At the end of April dyspnœa and restless nights returned and on May 7th she was unable to lie down. There was then dulness at both bases up to the angle of the scapula. On the 9th I drew off 23 ounces of very sanguineous fluid from the left pleura; it gave immediate but partial relief and she sank and died next evening (May 10th).

The great veins at the root of the neck are preserved in the Middlesex Hospital Museum and the specimen is thus described in our catalogue: "The veins of the neck and the superior vena cava. The superior vena cava is occupied by clot which projects into the right auricle. The innominate, subclavian, and jugular veins are completely blocked by clot and converted into fibrous cords. On the left side there is considerable matting about the upper end of the jugular vein. The azygos vein is enlarged. From a girl, aged 12 years, in whom the condition ensued five months after an attack of enteric fever. Double hydrothorax was present."—(Specimen shown.)[2]

---

[2] Middlesex Hospital Medical Register, 1155, 1893, P.M. 105, 1894.

The second case was one that I saw four times in consultation with Dr. O. Percival White and Dr. Norris. The patient was a married lady, aged 30 years. During the seventh month of her first pregnancy accidental hæmorrhage occurred and the child was born dead on May 12th, 1900. She passed through the puerperal state quite normally. At the end of four weeks she went away to Folkestone and about a week later she developed a thrombus in the right internal saphena vein. Two months later—July 9th—she returned to London. Dr. White found her looking extremely ill, with a much higher pulse-rate than he could account for. Her temperature was 100° F.; the right saphena vein was still tender and firm. On July 16th she complained of pain in the right side of the neck. As there was an old-standing small thyroid adenoma here it was thought that this might be the cause of the trouble. But when I saw this patient again on July 19th there was no doubt whatever that clotting had occurred in the right axillary, subclavian, and external jugular veins—these could be felt as firm and very tender cords. There was marked venous congestion and œdema of the right hand and arm and the patient complained of extreme pain in these parts. The œdema of the upper limb and right side of the chest became enormous, but by the end of the month the œdema and the pain had both become less, although it was clear that the internal jugular vein was also plugged and the patient complained much of buzzing in the ears as well as of the intense pain in the arm. The right arm gradually got perfectly well. Then the same process was gone through on the left side, but the pain and the circulatory disturbance did not seem to be quite so severe. At the end of August fluid was discovered in both the pleural cavities and these were repeatedly tapped, clear serum being drawn off. The relief afforded was only transient and on Sept. 12th the patient died. The cause of the pleural effusions would appear in this case to have been venous engorgement only, due to obstruction of the azygos veins. In the former case there was evidently injection of the pleura with a pyogenic organism; it was not a hydrothorax but an empyema.

The Ingleby Lectures

ON

CHRONIC HYPERTROPHY OF THE FAUCIAL AND PHARYNGEAL LYMPHOID OR ADENOID TISSUES.

Delivered at the University, Birmingham,

BY F. MARSH, F.R.C.S. ENG.,

SURGEON TO THE QUEEN'S HOSPITAL AND TO THE EAR AND THROAT HOSPITAL, BIRMINGHAM.

LECTURE I.

Delivered on May 27th.

MR. DEAN AND GENTLEMEN,—It is customary and very right that at the commencement of these lectures some reference should be made to keep alive the memory of him who founded and endowed them, the late Dr Ingleby. He was born at Cheadle in Staffordshire in 1794. He was apprenticed to a medical man there for five years. He then went to the London and Edinburgh medical schools and came to Birmingham in May, 1816, being appointed surgeon to the General Dispensary in August of that year. In 1828 he became lecturer on midwifery in the School of Medicine and not a little of the reputation of Queen's College was due to him. He acquired a very extensive and important practice and as an obstetric practitioner he stood alone in the provinces. His opinion was sought by patients from London and all parts of the kingdom. As an author in midwifery he was without a rival and he gained a European reputation by his work on obstetric medicine. He also wrote a book on Uterine Hæmorrhage and published a course of clinical lectures in THE LANCET. As a lecturer he had no pretensions to eloquence or to fluency; he never talked learnedly but used good Saxon words with taste and precision, his *forte* being description and detail. He was a man of no display and in consultation was unassuming almost to a fault, careful to a degree not to place a practitioner in any difficulty. He was never heard to speak with discourtesy or disparagement of any fellow practitioner. In private life he was singularly amiable and gentle and was never known to be angry, although he was remarkably nervous and excitable. A case of unusual severity would spoil both his slumbers and his appetite. He suffered nothing to interfere with his practice and he pursued it with the enthusiasm and fate of a martyr. He laboured not wisely but too well and slowly but certainly his health gave way under the pressure of habitual fatigue. Nothing, however, would induce him to take even a temporary rest and not until the mischief was beyond a remedy did he see how fatally he had trifled with his life. For six weeks prior to his death he suffered from occasional attacks of atonic gout, clearly the consequence of his extreme abstemiousness and over-toil. He was again advised to rest, to take more nourishment, and to undergo a course of treatment. This advice, though consistent with his own opinion, was utterly disregarded. In this condition a feverish cold further depressed his vitality and an attack of pleuritis followed on the 24th of January, for which he was bled, leeched, blistered, and purged. The inflammation ran on to effusion, when its severity subsided, leaving its subject in an exhausted, dying state. A slight rally was followed by an attack of meningitis and by death on the 28th of January, 1845. Thus perished prematurely, at the age of 50 years, one of the brightest ornaments of our profession and one of the most amiable, useful, and esteemed members of society—a victim to an undue devotion to study and to the duties of his immense practice. This brief outline of his life and death conveys to us both an example and a warning—so plain that he who runs may read. Could he but speak to us from the land of the beyond the warning would be his theme. I pray you to give heed to the example.

In accordance with the wishes of the founder I purpose to speak of conditions peculiar, at all events to a great extent, to childhood—viz., Hypertrophy of the Faucial and Pharyngeal Lymphoid or Adenoid Tissues. I have selected this subject as being one of great interest to those engaged in the general work of our profession and as one upon which I am able to speak with some authority. Although I have not much that is new to bring before you at the present time I feel there is much that needs saying upon the subject.

The structure of these lymphoid tissues consists of a network of loose connective tissue in the meshwork of which are lymphatic follicles and also, according to Sajous, some conglomerate glands. They are covered with cylindrical epithelium and are richly supplied with blood-vessels. They occur as distinct and well-defined rounded masses between the anterior and posterior pillars of the pharynx—the faucial tonsils—as an irregular layer across the upper part of the posterior wall and vault of the naso-pharynx—Luschka's tonsil—and as scattered patches over the posterior and lateral walls of the pharynx, sometimes in the latter situation extending downwards as distinct bands from Luschka's tonsil, behind the posterior pillars of the pharynx. There are also two patches at the base of the tongue in the glosso-epiglottidean fossæ known as the lingual tonsils but which are outside the scope of these lectures. These tissues during inflammatory catarrhal attacks increase in size and are also very prone under certain conditions to overgrowth or hypertrophy—and it is this latter condition alone as distinct from the former that I purpose to speak about.

The faucial tonsils when hypertrophied are generally spoken of as "enlarged tonsils." Hypertrophy of Luschka's tonsil has gone by many names: "adenoid vegetations in the naso-pharynx," "adenoid growths," "post-nasal growths" (or "growths" for short), "post-nasal adenoids," and now "adenoids." This last is a short and convenient name, and so long as the true nature of the condition is kept in mind there can be no valid objection to its general use. "Enlarged tonsils and adenoids" is now a common way of denoting this hypertrophy of the two groups of tonsils. Hypertrophy of the scattered patches and lateral bands in the pharynx is usually termed "chronic follicular or granular pharyngitis." It may be said that there is practical agreement that enlarged "tonsils and adenoids" are usually associated, that they occur essentially in childhood and adolescence, and that they are almost equally prevalent in the two sexes. Considerable diversity of opinion, however, exists as to the influence or importance of most of the assigned causes—viz., heredity, scrofula, lymphatic temperament, climate, anterior nasal stenosis, cleft palate, vaginal secretions at birth, the acute exanthemata, whooping-cough, and nasal and naso-pharyngeal catarrh. Heredity (including both the transmission of a special tendency to this hypertrophy, of which some well-marked instances have come under my notice, and the liability of children with a tuberculous family history to lymphatic affections) is certainly a cause, and that it may be the only one is shown by the occasional manifestation of the symptoms from the time of birth. Climate is undoubtedly a most important factor. The atmosphere in large cities and for miles around is laden, more or less, with irritating ingredients—particles of carbon, acrid fumes, &c.—and the constant passage of these impurities over these tissues so sensitive to stimulation is sufficient in itself to produce over-growth. Add to this a winter climate—though the word "winter" might almost be omitted—of rapid alternations of temperature, periods of cold winds, wet, fog, and gloom, with only occasional intervals of dryness and sunshine, and you have ideal conditions for the production of acute catarrhal inflammations—rhinitis, adenoiditis, and tonsillitis. Let only these attacks be repeated, or, above all, neglected, as is so often the case with the masses, and you soon have a chronic tonsillitis and adenoiditis with the inevitable hypertrophy as a sequel. A cold, moist climate, clay subsoil, &c., is a sufficiently exciting cause altogether apart from the effect of the vitiated air of large towns. Measles, scarlet fever, whooping-cough, and influenza are active exciting causes, the first symptoms often dating from one of these illnesses. Anterior nasal stenosis is considered by some authorities to be a predisposing and even an exciting cause of adenoids, but a careful examination of a very large number of children with adenoids sufficient to cause almost complete nasal stenosis has shown the nasal fossæ to be generally patent, and only stenosed anteriorly in cases where catarrh has been present as well. In fact, my observations have led me to the conclusion that anterior stenosis from turbinate congestion, &c., is either concurrent with an adenoiditis or a result rather than a cause of the hypertrophy. Deflections of the septum sufficient to cause anything like complete stenosis are very rare in children. To sum up, heredity, bad climate, bad hygiene, bad feeding, and neglected colds will account for the majority of cases.

The age at which the hypertrophy takes place, or rather causes symptoms requiring treatment, is shown by the following table of 1000 cases operated upon by me at the Birmingham Ear and Throat Hospital from Jan. 1st, 1899, to Jan. 15th, 1902—a little over three years. Of the 1000 cases 556 of the patients were females and 444 were males, and 816 were under and 184 were over 16 years of age. The youngest patient was 14 weeks old and the oldest was 36 years old.

Table of 1000 Cases of Hypertrophy Operated upon at the Birmingham Ear and Throat Hospital between Jan. 1st, 1899, and Jan. 15th, 1902.

Age.	Number.	Age.	Number.
In the first year	9	In the eleventh year ...	37
" second year	17	" twelfth year... ...	57

" ninth year	51	Over 16 years of age ...	184
" tenth year	53		
			1000

An analysis of the 816 cases among patients under 16 years of age shows that the greatest number were in their fifth year, those in their sixth, fourth, and seventh years ranking next. Considerably over one-third, therefore, of the 816 cases occurred in these four years.

Although in children enlarged tonsils are nearly always associated with adenoids it will be most convenient to consider the special characteristics, symptoms, and treatment of each separately.

The clinical importance of enlarged tonsils has been recognised for a great number of years, but symptoms were assigned to them which were in reality due to adenoids—then unknown. Consequently, tonsillotomy often failed to give more than partial relief and became to some extent discredited. Disappointed parents attributed to the operation the poor development of the thorax, the sexual organs, and mammæ in girls, and the tradition still lingers. An occasional protest against removal of the tonsils is still made on these grounds.

In size, shape, and consistence enlarged tonsils vary much, but they may be arranged in three groups: (1) where the hypertrophy is chiefly in the horizontal diameter—the projecting tonsil; (2) where the hypertrophy is chiefly in the vertical diameter—the elongated tonsil; and (3) where the hypertrophy is chiefly in the antero-posterior diameter—the broad sessile or flat tonsil. These types may, and often do, approach each other and are found in combination with one another, the most frequent being the elongated with the projecting. This occasionally has in exaggerated forms the appearance of a double tonsil. This is probably due to the persistence of the lower of the two furrows which, according to Killian,[1] are present at birth. Persistence of the upper furrow is more common and without careful examination its circular edge might be mistaken for the edge of an excavated ulcer.[2] The surface of the tonsils may be even and of a fairly normal aspect or ragged with large and irregular openings into the crypts. Very rarely it is papillated, as in these two tonsils removed from a girl, aged five years, where the surface is covered with projecting papillæ, some half an inch long, and presents an appearance that might be mistaken for multiple papillomata. The consistence may be normal, dense and fibrous, or soft and mushy, according to the predominance of the fibrous or lymphoid tissues. The older the patient the more fibrous the tissues, as a rule, but much depends on the occurrence and length of chronic inflammatory attacks. The secretion from the follicles may be caseating and retained in the crypts and recesses of the tonsils. The pillars of the fauces may from previous inflammatory attacks be more or less adherent and in marked cases almost blended with the tonsils, especially in the sessile variety.

The symptoms caused by enlarged tonsils may be classified as (1) obstructive, (2) catarrhal, and (3) reflex.

1. *Obstructive symptoms.*—The size alone of the tonsils may cause considerable mechanical trouble. Swallowing when the projecting tonsils are in apposition is rendered difficult—a special effort has to be made by the child to get the food out of his mouth and in extreme cases fluid only can be swallowed and that with difficulty. Under similar conditions buccal respiration is much impeded (a serious matter if nasal stenosis from adenoids coexists) and the voice is thick and indistinct. In some cases the palate is pressed upwards to such an extent that the action of the palato-tubal muscles is impeded and deafness results from imperfect middle-ear aeration.

2. *Catarrhal symptoms.*—The crypts and recesses, especially in those forms where lymphoid tissue predominates, are suitable places for the lodgment of the catarrh microbe—the pneumococcus and other micrococci akin to it—and form "centres" for catarrhal attacks. The microbe, probably ever present, waits only for some diminution of tissue resistance, such as an exposure to cold will produce, to exert its maleficence. The catarrh may either keep localised, causing tonsillitis and exaggerating or producing obstruction, or in those of less resisting power may extend to adenoids, if present, causing adenoiditis, and from there to the middle-ear or to the nasal cavities or downwards to the organs of respiration and digestion, according to the constitutional peculiarity or tendency of the individual. Owing to absorption of toxin generated by the catarrh microbe or the passage of the microbe itself through the lymphatics, the lymphatic glands corresponding to the tonsils (the upper set of the deep cervical group) often become inflamed and enlarged. In the slighter cases the glands enlarge during catarrhal attacks and subside with the disappearance of the catarrh. In others the glands do not disappear on the subsidence of the catarrh but remain distinctly enlarged and become larger and tender on pressure during every subsequent catarrhal attack but with little or no tendency to break down or to suppurate. In the more severe cases there is from the first a decided tendency for the glands to break-down and to suppurate. This variation is due to the difference in the resisting power of the individual and the intensity and amount of the toxin absorbed. Tonsillotomy prevents these attacks and if promptly done at the outset may arrest the progress towards suppuration. Glands, too, that have been enlarged for a considerable length of time often gradually diminish in size and disappear after tonsillotomy. The two following cases illustrate this and the possible arrest of suppuration.

---

[1] Archiv für Laryngologie, vol. vii.

[2] Dundas Grant: Brit. Med. Jour., vol. ii., 1901.

Case 1.—The patient, a boy, aged 14 years, with a good family history, was seen on Nov. 5th, 1900, for enlargement of the right upper cervical glands of some years' duration, one of them being of the size of a small hen's egg, painless, but becoming larger during colds and tender to pressure. Treatment had been of no avail and tonsillotomy had been done at Cape Town. The right tonsil was, however, very large, with a ragged surface, the adenoids were in a similar condition, and patches of hypertrophied lymphoid tissue were scattered over the pharynx. Right tonsillotomy and removal of adenoids was advised and performed, and after recovery from the operation the pharyngeal patches were cauterised. This was followed by gradual diminution of the glands and the patient's mother reported on Feb. 17th, 1902, that they had completely disappeared.

This is an extreme case and it was a question at the time of operation if the glands should not then be excised but the mother wished to await the result of the simpler procedure and was much gratified at the result.

Case 2.—A healthy child, aged six years, living in the country, was seen on Nov. 22nd, 1900, for enlargement of the left upper cervical and parotid sets of glands—a sequel of a cold contracted a fortnight previously. Twelve months ago a similar condition happened on the right side and was followed by suppuration of the glands necessitating incisions. On the right the scars were well marked and one was adherent to a hard nodular gland. On the left side a mass of glands, tender when touched, formed a prominent swelling below the left ear and the angle of the jaw. Both the tonsils and adenoids were large and soft but were not inflamed. As no fluctuation could be detected a hope was held out that suppuration might be prevented by immediate tonsillotomy and curetting of the adenoids. This was done and in a few days there was a marked diminution in the swelling and in a fortnight it had practically disappeared, though a few of the glands remained slightly enlarged for a few months. The child was seen again a year later for a reopening of the scar over the nodular gland on the right side, but the left side remained perfectly well.

These enlarged glands have been, and, indeed, are now, often termed tuberculous, greatly to the alarm of the parents. That they are not tuberculous is probable by the absence of extension to neighbouring glands, by the absence of systemic infection, and most of all by the satisfactory result—in the great majority of cases—of treatment directed to the tonsils. I wish particularly to impress upon you that in those cases it is the tonsils and not the glands which need treatment.

3. *Reflex symptoms.*—The only reflex symptom that I have been able to attribute to enlarged tonsils is "cough." This may be short, dry, or hacking in character and almost constant, or occurring in paroxysms and distinctly spasmodic in character. It is difficult when "adenoids" are also present to say to which group the credit of the reflex should be given, but every now and then cases occur—such as the following—which seem to point definitely to the tonsils as a cause.

Case 3.—A boy, aged six and three-quarter years, was sent to me by Dr. Alexander Bryce on Sept 7th, 1900 The chief symptom complained of was "cough" which was frequent, croupy in character, and not benefited by treatment. The breathing was noisy at night. The tonsils—the left one especially—were enlarged and the surface of both was ragged. There were slight adenoids. I endorsed Dr Bryce's opinion that the tonsil condition was the cause of the cough and a few days later did tonsillotomy and curettement of adenoids, completely curing it.

Case 4.—A boy, aged five years, was sent to me by Dr. Tildesley on Sept. 18th, 1900, for constant hacking cough, worse at night and causing restlessness and disturbing sleep. There was no thoracic cause or nasal obstruction or deafness. Both tonsils were enlarged and were soft in consistence and there were slight adenoids. Tonsillotomy and curetting of adenoids was done on the following day and the cough rapidly got well.

The diagnosis is simple. The possibility of tonsillitis accounting for the whole or part of the symptoms must be kept in mind; the presence of febrile symptoms and the inflamed aspect of the tonsils will clear up this point. A thorough examination should in all cases be made, the surface and condition often being of more importance than the actual size. When the examination has been completed (which should include the buccal cavity, pharynx, nasopharynx, nose, ears, and lymphatic glands) the tongue depressor should be pressed backwards until the child retches; this brings the tonsils into relief and, especially in the flat forms, shows their full extent and condition.

The treatment resolves itself into the question of operation or not. The fact that the tonsils project a little more than is usual does not render tonsillotomy either necessary or advisable. It should be undertaken solely for the relief of some definite symptom or symptoms which cannot be satisfactorily treated by other means.

I consider operative treatment necessary when the tonsils are so large that they mechanically cause some obstructive symptom, even if otherwise healthy—when they are the centres for frequent or prolonged catarrhal attacks or acute inflammatory attacks, when they are the cause of lymphadenitis; when the crypts and recesses are filled with caseating secretion which does not yield to treatment; when they are the probable cause of a troublesome reflex cough. I consider it advisable when an adenoid operation is necessary even if the hypertrophy is not very marked

The operation of tonsillotomy in children is now seldom performed except under an anæsthetic and in conjunction with an adenoid operation The question of the anæsthetic, therefore, will be dealt with when the latter question is considered. Tonsillotomy alone may, however, be necessary in older children. Then local anæsthesia induced by applying a 10 per cent solution of cocaine or eucaine is all that is needed, but if the child is nervous and sensitive nitrous oxide gas may be employed and will give ample time.

Various methods have been devised for the removal of the enlarged tonsils—a blunt-pointed bistoury and vulsellum forceps were used in early times and are still by some surgeons. The operator stands in front of the patient, seizes the left tonsil with the vulsellum forceps which are held in the left hand, and draws it towards the middle line and removes as much tonsil as possible by cutting upwards with the bistoury If the surgeon is ambidextrous the right tonsil may be removed in a similar manner, the forceps now being held in the right hand; but if not ambidextrous it will be necessary for him to stand behind the patient. For a tractable child with projecting tonsils this method may be satisfactory, but the combination is not a common one and doubtless it was to overcome this difficulty that guillotines were invented. The earliest forms were very ingenious and consisted of a concealed ring knife and a transfixing spear, so attached that the tonsil was levered inwards whilst the ring knife cut through it. I am under the impression that the credit of this inception should be given to a French surgeon named Matthieu. His name is still associated with the instrument, although there have been many modifications with many names attached to them—Luer, Bosking, &c. To the late Sir Morell Mackenzie we owe the introduction of the spade guillotine and this type, though modified in many ways, and not always to the improvement of the instrument, has nearly displaced the French one. It is simple in construction and can be used with the patient in any position and with or without light. If properly used no difficulty will be found in removing the greater part even of the flat forms of tonsils. In my own practice I always use Mackenzie's pattern, from five to six inches in length, and with a well balanced metal handle. The method of using it is all important If the patient is in the sitting posture the head must be steadied by an assistant who must make steady pressure just beneath and behind the angle of the lower maxilla at the time of the removal of the tonsil The operator should stand in front of the patient for the removal of the left tonsil, to the right and slightly behind for the removal of the right tonsil, unless he is ambidextrous or has a reversible handle to the guillotine. The guillotine should be warmed by dipping it in hot water The first step is the proper engagement of the tonsil and here care must be taken to first encircle the lower edge. The second step is to press firmly the guillotine outwards and the third to press sharply home the blade with the thumb. These movements though distinct should be performed almost as one—steadily but rapidly

The causes of inefficient removal or failure are due generally to a non-recognition of the first two movements and to the use of too large a guillotine, or more rarely to adhesions between the tonsils and the pillars of the fauces preventing proper engagement with the guillotine. When this latter is the case it is sometimes necessary to separate the adhesions prior to tonsillotomy. After removal the severed tonsil generally adheres to the guillotine and very seldom gives trouble by falling into the patient's pharynx.

even in the lying down position. If the patient is in this latter position both tonsils can be removed by the operator standing on the right side or behind the head for the removal of the right tonsil if he prefer. If the patient is under an anæsthetic a gag must be used and it may be necessary to change it to the other side of the mouth after the removal of the first tonsil. If, however, it is carefully placed and managed by an anæsthetist who has had experience in these cases the change is seldom required. In a combined tonsil and adenoid operation the question arises which should be first removed. This depends upon the size of the tonsils; if these are so large that they would interfere with the free exit of the curette or other instrument with the adenoids they must be operated upon first, but if not it is better first to remove the adenoids.

After the operation no portion of tonsil should be seen projecting beyond the pillars of the fauces—preferably there should be a distinct hollow. Removal of a superficial slice is not enough; the greater part of the enlarged tonsil must be removed, a small pad only being left. It has happened to me on three or four occasions to enucleate completely a tonsil with the guillotine, the blade—probably not over-sharp—slipping over a convex surface not so embedded as usual. I have not known of any detriment following this, such as lodgment of particles of food in the hollow left, injury to the internal carotid by a sharp fish or other bone caught between the pillars of the fauces, or undue approximation of the pillars of the fauces. These are possible consequences and to obviate them a small pad of tonsil tissue should be left.

Other methods of operation—viz., with tonsil scissors, the cold wire snare, the écraseur, the galvano-cautery snare, morcellement, and crushing—may be occasionally advisable in adults, but as yet I have not found it necessary to adopt any of them in children. In a few cases in older children I have, when tonsillotomy has been much dreaded by anxious parents, employed ignipuncture with the galvano cautery. A straight point is used and inserted into the substance of the tonsils, previously well cocained, at a bright red heat. It is not advisable to make more than two punctures at one sitting and usually three or four in all will suffice to achieve the desired result.

The risks of a well-performed tonsillotomy are practically *nil*. It is impossible to wound the internal carotid artery either with a guillotine or with a blunt pointed bistoury if ordinary care be used (a sharp-pointed one should never be used). The immediate hæmorrhage is at times free, especially if the whole of the tonsil is by any chance enucleated, but it generally ceases of itself, and I have never yet had occasion to tie a vessel or ever had any anxiety about it. Recurrent hæmorrhage—that is to say, hæmorrhage occurring within the first 24 hours after operation—is more serious; a large quantity of blood may be swallowed before the patient or the nurse is cognisant of it; in one or two instances I have known it continue to syncope before medical assistance could be obtained.

The first step in the treatment is to ascertain exactly the origin of the hæmorrhage, whether it is from a single vessel, in one or both tonsils, or a general oozing from one or both. If the former a pair of Spencer Wells forceps should be clamped on and left *in situ*, but I have never had occasion to do this in the case of children. If caused by a general oozing the bleeding surface should be well swabbed with adrenalin solution and chloride of calcium in from 5 to 10 grain doses, according to the age of the patient, should be given every hour until the bleeding stops. If the application of adrenalin does not suffice firm pressure should be made over the bleeding stump with a pad of lint, with or without adrenalin, and kept in position either by the finger or a pair of forceps, but I rely much on the calcium chloride. In one case where there was a distinct hæmophilic history I gave it for some days prior to the operation with a very satisfactory result and I now frequently give it to adults beforehand as a precautionary measure.

True secondary hæmorrhage is rare but it does occasionally take place even as late as the sixth day from the opening up of a small vessel during the separation of a slough. The following cases are illustrative of recurring and secondary hæmorrhage.

CASE 5.—The patient, a boy, aged 11 years, was operated upon at home on Sept. 8th, 1896, at 9.15 A.M., for much enlarged tonsils causing obstructive symptoms and for slight adenoids. Dr. G. Elkington and Dr. H. S. Wilson were associated with me in the case. Chloroform was given by the open method. There was less bleeding than usual at the time of operation although there was a predominance of fibrous tissue in the tonsil structure. The patient was carried back to bed and was kept very quiet all day. About 8 P.M., almost 11 hours after the operation, he commenced to swallow somewhat frequently and at 8.30 P.M. Dr. Wilson saw that blood was coming from the tonsils and applied a concentrated solution of tannin. This, however, did not prove effectual, as about 11 P.M. he vomited a large quantity of almost pure blood, certainly not less than two pints. A solution of perchloride of iron was now applied and the bleeding apparently ceased, the boy being blanched and almost in a state of syncope. I was sent for, but when I saw him at 2.30 A.M. the bleeding had ceased, the tonsils being coated with blood-clot and iron. The pulse-rate was 150 and barely countable. I remained in the house the rest of the night in case of need but there was no return of the hæmorrhage. His pulse-rate 24 hours later had fallen to 85 and he made a slow but good recovery.

CASE 6.—A boy, aged 14 years, overgrown and very stout and flabby-tissued, came to me on Nov. 9th, 1900, for removal of adenoids and enlarged tonsils, which were causing marked nasal obstruction and catarrhal trouble. The operation was performed in a private hospital. The bleeding was profuse at the time of the operation but soon ceased. He was carried carefully back to bed and his throat again examined but there was no sign of hæmorrhage. Some two hours later, however, profuse hæmorrhage set in; the blood was swallowed and vomited and a good deal came freely through the mouth and nose. I was summoned and found him blanched, almost pulseless, with sighing respiration, and still bleeding; this I found to be a general oozing from the tonsils. Suprarenal liquid with chloretone was thoroughly applied to the oozing surface, 10 grains of chloride of calcium were given every hour, and a saline enema was slowly administered. Bleeding soon ceased and did not recur and the boy made a good recovery. Had I to operate on a similar tissued boy I should now certainly give him a preliminary course of calcium chloride.

CASE 7.—A delicate girl, aged 11 years, was operated upon at home on Sept. 5th, 1900, in coöperation with Dr. F. W. Underhill, for enlarged tonsils and adenoids, causing right suppurative otitis media, cervical adenitis, and frequent catarrhal attacks. Nothing unusual occurred at the time of the operation, but Dr. Underhill noticed that subsequently the tonsil surface was more sloughy than was that of her brother who was operated upon at the same time. On the sixth day after the operation, as the weather was warm and sunny, the patient was out in the garden, running about, I expect, when she felt ill and faint. She came in and vomited a large quantity of blood; she was put to bed at once but vomiting and spitting out of blood continued. Messengers were sent for medical assistance and I was summoned. Before anyone arrived the child had bled to syncope and the hæmorrhage had ceased. I found her lying pallid and almost exsanguine. On examination a firm, adherent blood-clot was seen over the surface of the right tonsil and this I did not deem it advisable to remove. I ordered calcium chloride and made arrangements to be available in case of recurrence. Fortunately this did not happen and she made a good recovery, though for some time she was very anæmic. The hæmorrhage was clearly due to the separation of a slough opening up a small vessel.

Another risk, also a small one, is sepsis, with its probable complication septic pneumonia. It is impossible to sterilise the patient's throat prior to operation but possible sources of infection, such as carious teeth, alveolar abscess, &c., should be looked for and removed. Instruments can be and should be sterilised and the surgeon's hands rendered as aseptic as possible. Sponges, if used, should receive the most careful cleansing and sterilising; personally, I never use them but employ a swab of cotton lint wrung out of hot water for what mopping out is needed.

The patient's condition at the time of operation is also important. The operation is one of election and a time should be chosen when the patient is well and free from any febrile condition—when his tissues are in a fairly good state of resistance. The better his resisting powers the smaller the risk of sepsis. It need hardly be said, too, that the patient should be placed in the best hygienic surroundings that his circumstances will admit.

The treatment after operation is simple. The essentials are: (1) avoidance of exertion immediately afterwards (a fertile cause of recurrent hæmorrhage); (2) an equable temperature during the healing process (to prevent catarrhal attacks); (3) suitable diet; and (4) the use of a cleansing wash. The operation should therefore be performed at home or in a hospital and the child should be put straight to bed afterwards in a warm room and kept there for at least three days and indoors the rest of the week unless the weather is exceptionally warm. Nothing hot or hard should be given; the first day sterilised milk only—cold or lukewarm; slop diet the next two days; then if the child is doing well ordinary light diet. If the throat is very painful when swallowing one-twelfth of a grain of cocaine lozenge may be given before meals or the throat may be sprayed with a weak cocaine solution, but this is seldom needed. After food the mouth and throat should be washed out or sprayed with an alkaline antiseptic solution.

Should sepsis happen an examination will show the stumps of the tonsils covered with an ashy grey slough. The parts which surround the palate, uvula, and pillars of the fauces will be red, swollen, and flecked with whitish patches, the tongue will be furred, and the breath offensive, the cervical glands will be painful and enlarged, the throat will be painful, especially on movements of deglutition, febrile symptoms will be marked, and possibly ushered in with a slight rigor. When this happens a full dose of calomel should be given at once and after its action quinine or perchloride of iron. If the child is old enough and able to gargle the mouth and throat should be frequently washed out with an alkaline antiseptic wash, such as borax, chlorate of potash and thymol, or with solution of chlorine. If the child is unable to gargle the throat should be frequently sprayed with a similar solution and iodoform or one of its odourless substitutes insufflated over the sloughy surface. The strength of the child must be maintained by good nursing and feeding and a careful watch should be kept for any lung or other complications. A sloughy surface is often present in delicate children but without any spreading inflammation or febrile symptoms, and it clears gradually without special treatment as the healing progresses, and can hardly be called septic. Whenever sloughing occurs there is the possibility of secondary hæmorrhage during the separation process.

In the slighter cases where operation is not needed, and in the few that for some reason or other operation is inadvisable, local and constitutional treatment should be instituted; cleansing gargles or sprays should be used, followed by the application of astringents, glycerine and tannic acid, hydrastis, &c., and iodine and iron, cod-liver oil, malt, and hypophosphites should be given internally. A long stay at the seaside or in the country often brings about a remarkable change for the better.

[A number of illustrative specimens and instruments were shown at the end of the lecture.]

CONCERNING INJURIOUS CONSTITUENTS IN WHISKY AND THEIR RELATION TO FLAVOUR.

By Sir LAUDER BRUNTON, M.D. Edin., F.R.S.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL;

AND

F. W. TUNNICLIFFE, M.D. Lond.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON.

Some 18 months ago in these columns[1] we drew attention to the physiological action of furfural, a universal constituent of both raw and matured pot-still whisky, and also to the apparently different physiological effects of whisky containing and freed from aldehydes. Since then the successful application on the large scale of a method, indicated in our last communication, for removing the aldehydes from whisky during distillation has brought this subject prominently before pharmacologists and chemists. We therefore think that it will be not without interest to enter somewhat more fully into the probable effects of removing the aldehydes and the higher alcohols from whisky than was possible in our last article. More especially is this the case since it must now be regarded as established that *at least some* of the raw and offensive smell and taste of freshly distilled whisky are due to its aldehydes. The knowledge of this fact is directly due to our original investigations, and although these were initiated from a purely pharmacological standpoint, this by-result—viz., the effect upon the flavour of raw whisky of the removal of the aldehydes—is likely to be of practical importance.

As is well known, the whisky that is generally sold to-day is blended whisky—that is, a mixture of spirits of various kinds. Blending consists essentially of mixing whisky derived entirely from malt and made in a pot-still, often of very varying age, with so-called silent spirit, or spirit obtained by the fermentation of various materials and the distillation of the subsequent wort, this latter usually being accomplished in a Coffey-still—i.e., in a still provided with a rectifying column. Silent spirit is cheaper than pure malt whisky not only on account of the materials from which the former is produced but also because it requires less maturing.[2] Whisky, on the other hand, derived from malt and made in a pot-still is when raw a very nauseating and foul-smelling liquid. Upon being kept in wood for varying periods of time it becomes changed in character, the irritating smell and disagreeable taste disappearing and the spirit assuming, according to its original properties, a more or less marked bouquet. By suitably blending these two varieties of whisky the trade are able to produce a drinkable article at a relatively cheap price. The alcohol percentage is rendered more or less constant by dilution with water and the colour of the liquid is brought up to a uniform artificial tint by means of caramel or some other suitable agent.

From this very superficial sketch it will be evident that whisky can only very rarely be strictly termed pure, consisting, as it does, of a drink the basis of which is generally pure whisky, this latter being artificially doctored to suit the public taste and the distiller's pocket. It is essential to bear this in mind because an improvement by chemical means of the manufacture of whisky is apt on account of its title to create prejudice; this should not be so since subsequently to fermentation the whole manufacture of whisky, whether in pot-still or in Coffey-still, is essentially a chemical process, and if the chemistry of it cannot at the present time be followed step by step it is due in no small degree to the fact that the employés in distilleries are neither chemists themselves nor are they in the majority of cases even directed by chemists. When chemical knowledge has eventually permeated into the distilleries in the Highlands then we shall certainly know more of the minute chemistry of whisky than we do now.

In its essentially chemical character whisky differs at once from wine: a wine can go on "living" long after it is laid in the winebin, can live and change even up to the time it is poured into its penultimate resting-place—the wineglass of the consumer. In the ageing of wine we have biological and chemical processes to consider, in the maturing of whisky chemical and chemico-physical ones. Wine-producers have never hesitated to utilise all that physics, chemistry, and biology can do for them, champagne is frozen and wines are pasteurised and, if need be, sugared or plastered; the manufacture of whisky stands still, and distillers exorcising any improved method with the epithet "doctor" view with mistrust any technique other than the one adopted by their forefathers.

There are, however, other reasons more cogent than the above why any process for the improved manufacture of whisky should be welcomed by pharmacologists and, indeed, hygienists. It has been pointed out on many occasions that whisky is by no means free from injurious constituents other than alcohol. It is also true that whisky is not simply alcohol but differs very considerably from it, at least in taste. Whether it differs also pharmacologically is not so clear. There is no doubt that wines influence digestion according to their acidity, bouquet, &c., but this has not been shown with regard to whisky.[3] That the effect of whisky upon the system is simply that of its ethyl alcoholic content is perhaps not strictly true, though there is very considerable physiological evidence in favour of this thesis. Be this as it may, we all prefer, at least all whisky-drinkers, whisky to correspondingly diluted ethylic alcohol. The difference between the two is essentially one of so called by-products. It is also to the class of by-products that the injurious constituents of whisky belong. It is true that these substances are present in very small quantities. Our information, however, upon this point is largely derived from German sources. In Germany pot-stills are practically non-existent, and it is to whisky produced in these stills that our remarks especially refer.

---

[1] The Lancet, Dec. 8th, 1900, p. 1643.

[2] The amount of maturation required by silent spirit before it is fit for blending varies. The rectifying column is theoretically supposed to keep back from the distillate all substances boiling above 78° C. As the whole operation is conducted under considerable pressure this theoretical result is not always accurately attained. The usual rectifying apparatus seems to be more efficient in removing higher alcohols, &c., than in getting rid of some of the lower boiling point impurities; thus acetic aldehyde can generally be detected in patent still spirit but furfural with its boiling point of 162° is most rarely if ever present.

[3] Chittenden and his collaborators have made many experiments upon this subject. Their earlier experiments were made upon digestions in vitro and showed that in so far as whisky was concerned the only instance in which it differed materially from ethylic alcohol was in its influence upon pancreatic digestion. Here it exerted a marked inhibitive action, much greater than that produced by ethylic alcohol

That whisky does contain injurious substances other than ethylic alcohol is shown by the sudden death of an employé in a West of England distillery. This unfortunate man died suddenly after imbibing a quantity of "feints." A post-mortem examination revealed the fact that his stomach contents had a similar odour to amyl nitrite. Although there was no evidence of the chronic effects of alcohol upon the liver, &c., there was evidence of acute irritant poisoning. The medical man who reported the case inferred that death was probably due to amylic alcohol.[4] A sensation of throbbing and headache was recently experienced by one of the authors of this paper and others upon inhaling the vapour arising from the low-wines and feints in a pure malt whisky distillery.

If, then, certain of the by-products of whisky are injurious to the consumer the question naturally arises, Are these individual by-products necessary? If this question be answered in the negative the conclusion which must be drawn is that whisky would be much better without them. This matter is of further interest in that at least one of the assumed effects of maturation is to diminish the amount of these substances present. From this it follows that any improved method for the manufacture of whisky which prevents the formation of these substances or at least keeps them out of the finished product performs one of the functions of maturation. At the present time there is, however, some difference of opinion as to to what class of chemical substances the injurious constituents of whisky belong and as to the precise relation between them and those substances which give to whisky its characteristic and agreeable flavour. Many observers have shown that iso-amylic alcohol, the main constituent of the so-called fusel oil, is much more poisonous than ordinary ethylic alcohol. Analytical results, although discrepant,[5] point to the conclusion that the quantity of fusel oil in matured spirit is considerably less than that in the raw substance. Coincidently with this diminution in fusel oil during maturation the flavour of the whisky improves. The taste of fusel oil itself when suitably diluted is not, however, unpleasant and this substance is actually used for the purpose of giving a whisky taste to silent spirit. The amount of fusel oil calculated as amylic alcohol present in whisky, whether raw or matured, is practically always under 0·1 per cent., and it thus follows that although these higher alcohols are much more poisonous than ethylic alcohol, yet nevertheless in the quantities present they would under ordinary circumstances hardly affect to an appreciable degree the action of the spirit.[6] However, if they are not necessary whisky is better without them.

Acting upon the above assumption many attempts have been made to remove fusel oil from raw whisky. It is to be noted that these attempts have all been directed specifically to the fusel oil itself, although it is more than probable that certain other constituents to be considered below though not aimed at have been affected by these processes. The rationale of certainly the earlier of these processes has been to obtain rapidly that oxidation which is supposed, upon not very certain grounds, to take place gradually during so-called "natural" maturation. This artificial oxidation has been brought about by very varying methods, all of which, however, have not only promoted—as, indeed, does natural maturation—oxidation *per se* but also evaporation. It must be noted here that in the evaporation of a complicated liquid like whisky those substances will have the greatest tendency to escape which have the lowest boiling-point. The higher alcohols do not possess this property. Nevertheless, however high the boiling point of a given constituent of whisky may be some of it will escape. Under these circumstances it is difficult in judging of these artificial maturation processes, as indeed of so-called natural maturation, to know how much of the effect to ascribe to evaporation and how much to oxidation.[7] Recently, however, a process for the artificial maturation of whisky, primarily intended for the removal of fusel oil, has been patented which certainly owes its result entirely to forced evaporation. This process is certainly as successful, if not more so, than those combining evaporation with oxidation. We have had especial facilities of examining the product of this last-named process and there is no doubt that by means of it raw whisky is deprived in the course of half an hour or so of its raw and offensive smell. Analyses of the treated spirits show that the greatest change which they have undergone is a diminution in their fusel oil content.

If, however, we come to examine this so-called defuselised whisky we find that it approaches more or less closely to silent spirit, that is, pure ethylic alcohol, in character. In other words, the spirit has by the process lost some of the essential attributes of whisky. This fact leads us to a consideration of the relation between the higher alcohols and the bouquet-giving constituents of whisky. That there is a relation between these two sets of bodies is practically universally admitted since there is strong evidence that the alcoholic constituents of fusel oil, amylic, propylic, and butylic alcohols are largely concerned in the production of the compound ethers which have actually been isolated from whisky or old whisky casks. Valeric ether is one of the few bouquet-giving substances which has actually been obtained from grog.[8] Another substance having the aroma of jargonelle pears is butyric acetate. This is produced from butyric alcohol and acetic acid, the latter being formed by the oxidation of ethylic alcohol, either in the fermenting back or subsequently.[9]

It must not be assumed; however, that the substances above named are the only ones to which the flavour of good old whisky is due. Rich malt whisky when perfectly raw contains free acids of the fatty series and also compound ethers. There is further analytical evidence to show that the actual development of compound ethers in the cask during maturation is slight;[10] in other words, that it is the compound ethers which were originally present that bestow upon the matured whisky its eventual flavour. If we accept this view we must assume that the maturation of whisky consists not so much in a process characterised by the development through oxidation of bouquet-giving substances as in the disappearance or change in the nature of bodies which mask the flavour of the compound ethers originally present. One fact seems quite certain—viz., that a whisky originally poor in fatty acids and compound ethers never develops into a full-bodied whisky.

Another class of compounds present in whisky both raw and matured and which have up to the present attracted but little attention are the aldehydes. The most recent process invented for the improvement of whisky manufacture consists in the extraction, by chemical means, of the aldehydes from the low wines. This is done by transforming them into hydrazones. These substances being non-volatile do not pass over upon the subsequent distillation of the

---

of the same strength. According to these observers, however, subsequent experiments made *in vivo* showed that the above experiments *in vitro* had not much practical value. *In vivo* whisky behaved practically identically with ethylic alcohol of the same strength.—Vide Chittenden and others. American Journal of Medical Sciences, 1896, January–April, pp. 35, 163, 314, 431, also American Journal of Physiology, 1898, vol. i., p. 164.

[4] Swain: Brit. Med. Jour., 1891, vol. i., p 903. It must be, however, noted with regard to this death that the "feints" consumed undoubtedly contained aldehydes, and that the poisonous nature of the aldehydes was apparently unknown to the author. The inclusion in this paper of an explanation of technical terms would render it too long; the reader is referred on this subject to, *inter alia*, the following.—Allen, Commercial Organic Analysis, vol i., Matthews, Alcoholic Fermentation; and Moercke, Handbuch der Spiritus Fabrication.

[5] Allen · Evidence before Select Committee, 1891. Also Bell Evidence before same Committee.

[6] In some analyses at present unpublished and made while this paper was passing through the press, the percentage of higher alcohols reached 0·25 per cent.

[7] These considerations are especially of interest with regard to furfural or the compound ethers. Furfural boils at 162°, ethyl acetate at 73° (lower than ethylic alcohol), and amyl acetate at 137° (*vide infra*).

[8] Lindet: Comptes Rendus, cxii., 102. Allen. Organic Commercial Analysis, vol. i., p. 149.

[9] Another consideration which should not be neglected in this connexion is that these higher alcohols are biological as distinguished from chemical products. They are produced in the fermentation backs at the end of fermentation and probably depend for their origin chiefly upon those conditions of yeast life occurring as a consequence of the disappearance of the sugar. Further, the species of ferment used seems to affect the character of the higher alcohols produced.

SOCIETIES.

TUESDAY (8th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. F. J. Poynton and Dr. A. Paine: A Contribution to the Study of Malignant Endocarditis.—Dr. W. Ewart and Mr A. S. Morley: The Possibility of Recovery from the Active Stage of Malignant Endocarditis (illustrated by cases and specimens)

WEDNESDAY (9th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 P.M. Clinical Evening.

THURSDAY (10th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—Specimens will be shown by Dr. H. M. Jones. Paper:—Dr. H. Croom: The Secondary Aspects of Deciduoma Malignum.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Papers:—Dr. R. Bowles: The Practical Treatment of Functional Vasomotor Disturbances.—Mr R. Johnson: Some Points in the Treatment of Tuberculous Disease of the Knee.

FRIDAY (11th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. T. Carwardine: Cases illustrating the Mode of Origin of certain Cysts of the Neck.—Dr. W. J. Tyson: Case of Intestinal Obstruction due to Embolism of a Branch of the Superior Mesenteric Artery.—Mr A. E. Barker: Cerebellar Abscess with Sudden Paralysis of the Respiratory Centres.—Mr. H. L. Barnard: The Simulation of Acute Peritonitis by Pleuro-pneumonic Disease.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. W. Wingrave, Dr. W. H. Kelson, Dr. StClair Thomson, Mr. A. H. Cheatle, Dr. Lack and others.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi terrace, Strand, W.C.)—7.30 P.M. Discussion on the Tenure of Office of Medical Officers of Health.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. M. H. MacLeod: Clinique. (Skin.)

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

TUESDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Taylor: [illegible] (Medical.)

WEDNESDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. [illegible] Clinique. (Surgical.)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on the Prevention of Malaria (opened by Dr. P. Manson).

THURSDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Clinique. (Ear.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of *THE LANCET have for many years paid, and continue to pay,* the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from [illegible] places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—T[illegible]NAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

low wines; by this means the raw whisky is rendered entirely free from aldehydic bodies. The interesting point of this process is that by means of it only the aldehydes and the acetals (compounds of the aldehydes with alcohols) are removed; the higher alcohols, fatty acids and compound ethers are left intact. Raw whisky treated in this way loses practically entirely its pungent and irritating taste and smell. This fact must lead us to reconsider the view which has been up to the present universally adopted—viz., that the characteristic smell and taste of raw whisky are due to the higher alcohols. This obviously cannot be so, as the new whisky produced in the above manner—i.e., from dealdehyded low wines—although containing the higher alcohols has no pungent taste or flavour. We must, therefore, now ascribe the pungency of raw whisky either to aldehydes or to acetals.

Concerning the actual aldehydes present in whisky either raw or matured very little is known, until quite recently no accurate method of estimating them has been available. Concerning their amount it may be said that as much as 20 milligrammes of aldehydes have been found in 100 cubic centimetres of German Branntwein.[11] One aldehyde, however, furfural, has for a long time attracted the attention of chemists and pharmacologists. The reason for this most probably is that this substance gives a very delicate colour reaction by means of which its presence even in the most minute traces can easily be detected.[12]

Furfural in dilute solutions has a taste which is not unpleasant and resembles that of benzaldehyde. This latter substance has a taste of bitter almonds and is constantly used for flavouring liqueurs and artificially concocted brandies and other spirits. Benzaldehyde is distinctly poisonous and its use for this purpose is not to be recommended. Furfural has been the subject of a good deal of pharmacological work.[13] It is about 50 times as poisonous as ordinary ethylic alcohol and gives rise in adequate quantities to epileptiform convulsions, general muscular paralysis ending in paralysis of the respiratory muscles, and death. In the body furfural is oxidised to pyromucic acid, which substance is physiologically inactive. The symptoms to which furfural gives rise are practically the same in all animals, but with regard to dose pigeons seem most susceptible to its action. In the higher animals when given on an empty stomach it is absorbed almost as rapidly as when injected sub cutem and it gives rise to complete paralysis of voluntary movement. As the animal recovers from this epileptiform convulsions appear. These convulsions are probably due to irritation of the cortical motor centres and are thus brought into line with those caused by one of the constituents of absinthe. The exact origin of these convulsions is a matter of interest in that, speaking generally, drugs stimulating the cortical motor centres stimulate also the psychical centres. For instance, cocaine and belladonna exert a marked stimulating action upon the cortical motor centres, the effect, however, not extending to convulsions but manifesting itself in restlessness. In larger doses both these drugs, especially belladonna, give rise to a mental condition characterised by mania of a very restless kind. Profound restlessness often follows the consumption of spirits and is difficult to explain simply as the result of ethylic alcohol. It is, further, a fact well known to alienists that epileptic mania, one of the most dangerous forms of mania of which we have any cognisance, often alternates in epileptics with true epileptic convulsions. The relation between mania and convulsions is tersely expressed by a leading alienist in adopting the term "ideational convulsion" for the former. Pure ethylic alcohol, so far as we know, causes neither mania nor convulsions. The class of bodies which we are now considering—viz., aldehydes—do universally cause convulsions, and there is also evidence that at least one aldehyde—viz., furfural—gives rise to great cerebral excitement, animals to whom it had been administered becoming possessed with "a kind of sad fury."[14] The fact that different kinds of alcoholic drinks produce when freely imbibed different mental states—gay, sad, maudlin, &c.—also points to the conclusion that it is probably the by-products contained in spirituous drinks, rather than the ethylic alcohol itself, which give the special timbre to the mentation of the drinker or drunkard.

These considerations are of some ethical interest in that crimes in public-houses, or, at any rate, committed by persons in the initial stages of alcoholic poisoning, are by no means infrequent. These crimes have two peculiarities: they are generally motiveless, at least when judged by the standard of the sane, and they are committed by persons who have taken sufficient drink to affect their minds but not enough to paralyse their muscles. This latter fact shows that the actual amount of alcohol consumed has not been great. The crimes seem to have been committed under the influence of some mental aberration. We know that alcohol paralyses control and therefore it is conceivable that supposing a man had a grudge against his neighbour, although he might normally be able by exercising control to keep his hands off him, yet if he took a glass of pure alcohol and then found himself in the same public-house with the obnoxious acquaintance the alcohol would have so paralysed his control that he would proceed to attack the object of his dislike. The case, however, is quite different when, as sometimes happens, the two combatants were until the liquor was drunk apparently the best of friends and then suddenly under the influence of distorted imagination fell upon one another, often with the most disastrous results. When arraigned before the magistrate the next morning the excuse made by the prisoner for his conduct is that he was under the influence of drink. He was, but we very much doubt whether he was under the influence of ethylic alcohol.

With regard to the presence in whisky of aldehydes other than furfural and their physiological action very little is known. Ordinary aldehyde was found in a 25 years' old brandy to the extent of 0·0003 per cent.[15] Compound ethers, chiefly ethyl acetate, were present in the same brandy to the amount of 0·042 per cent. Acetic aldehyde (CH_3COH) has physiologically an irritant action upon all the mucous membranes and when absorbed causes, first irritation of the central nervous system and subsequently complete anæsthesia. Death takes place from asphyxia due to respiratory failure. Another aldehyde present in raw spirit is croton aldehyde.[16] This substance is also poisonous and when taken in approximately the same quantities as furfural causes great irritation and strong tremors. These tremors are of interest with regard to the work of Sten Stenberg[17] who investigated the difference between the acute alcoholic intoxications produced by raw potato spirit, potato spirit purified by being filtered through charcoal, and pure ethylic alcohol. All the liquids given contained equal quantities of ethylic alcohol, so, therefore, the difference between them was presumably simply one of by-products. The difference in the symptoms produced was not great; it was *a priori* to be expected that it would not be. Nevertheless it is evident from the experimental protocols, though apparently unnoticed by the investigator himself, that the occurrence of tremors was more common in the case of the raw potato spirit and the potato spirit purified by means of charcoal than in that of the pure ethylic alcohol. Experiments made recently[18] upon acute alcoholic intoxication by means of ordinary and dealdehyded spirit have shown that the return from the state of intoxication to the normal is different in the two cases, being in the case of the spirit containing aldehydes longer and accompanied by secondary symptoms—e.g., refusal of food, restlessness, and bad temper.

These specific facts, taken into consideration with the general physiologico-chemical properties of the aldehydes, especially their tendency to form compounds with proteids differing essentially from the original substances[19] and the fact that even if taken in doses apparently incapable of producing symptoms they are oxidised in the body to acids and thus diminishing the alkalinity of the blood tend to produce the phenomena of acid intoxication, certainly lead us to the conclusion that if they are not necessary for the production of whisky they are much better out of it.

This leads us to a discussion of the manner and the extent of the relationship, if any, between the aldehydes and the bouquet-giving substances in whisky. It must first of all be noted in this connexion that whisky produced from de-aldehyded low wines will be freed from both aldehydes and also acetals. It behoves us, therefore, to consider the probable effect upon the ultimate bouquet of whisky of the removal of both these classes of bodies. There can be no doubt concerning the effect of this treatment of the low wines upon the immediate taste of the whisky. Instead of the whisky appearing as a nauseating and irritant liquid it occurs certainly as an inoffensive drink. Alhehydes as such, speaking generally, are not possessed of an agreeable flavour. The lower aldehydes are, of course, notoriously irritating and so must those, *ex hypothesi*, be which are removed from raw whisky. This can easily be demonstrated by decomposing with dilute mineral acid the hydrazones formed by treating raw whisky with phenyl-hydrazine-sodium-sulphonate and left behind upon subsequent distillation. The original aldehydes are by this method liberated and have a pungent and irritating odour closely resembling that of the original whisky. With regard to the higher aldehydes it is known that in certain instances they occur as a constituent of the ethereal oils of certain fruits. Our knowledge upon this subject, however, is indefinite, although there seems no doubt that two substances known as citral and citronellal are used extensively in the manufacture of artificial perfumes. These substances, however, have never been demonstrated in whisky, raw or matured, and there is no reason to assume that they play any part in its flavour.

It is a known fact that there is now on the market a large assortment of artificially concocted fruit essences. These are largely used in the manufacture of so-called temperance beverages and in cookery, and they impart to the substances to which they are added a flavour almost identical with the fruit, as indicated on the label, to which they correspond. Although the composition of some of these essences is kept a secret the ingredients of the majority of them are known. The compound ethers are their most important constituents and are almost invariably associated with glycerine and occasionally with tartaric, succinic, or benzoic acids. Aldehyde—acetic aldehyde—is also made use of in some of these preparations, but it is difficult to see what purpose it serves, as it is admitted that both it and chloroform, which is also used, can be omitted without serious detriment to the flavour of the essence.[20] A study, then, of the composition of these essences leads us to the conclusion that aldehydes, speaking generally, are not likely to be intimately concerned in the development of bouquet.

With regard to the acetals it is an undoubted fact that these substances are intimately associated with the development of bouquet in wine. As was, however, pointed out earlier in this paper no analogy can *a priori* be assumed between the ageing of wine and the maturation of whisky. That the bouquet of mature whisky owes little, if anything, to acetal is certainly to be assumed from the fact that although it has been recognised as a constituent of mature spirits one of the greatest workers in this country upon this subject frankly asserts that he has never been able to demonstrate its presence in either raw or mature whisky. Nobody, so far as we know, has ever isolated it from raw whisky. With regard to the acetal corresponding to furfural we have no knowledge nor have we been able to obtain any information. That furfural undergoes but little change during maturation is evident from the fact that the quantitative estimations of it in raw and mature whisky differ but slightly. This difference, furfural apparently diminishing with age, can certainly be explained by its evaporation—the assumption that some furfural has been fixed or oxidised is

rely gratuitous. It must further be remembered that the

are unstable bodies and in the presence of dilute

dily decompose into the corresponding alcohol and

CONCLUSIONS.

ve considerations we seem justified in con-

aldehydes to which the initial irritating taste and flavour of raw pot-still whisky must be ascribed are only indirectly—viz., by their disappearance—concerned with the ultimate bouquet of old whisky. It further appears that since at least some of the energy of maturation is spent upon the disappearance of these substances it is probable that an initially dealdehyded spirit will become mature in a shorter time than an ordinary one. The last conclusion that we would draw is that since the aldehydes and furfural do not seem necessary for the production of whisky they are from the point of view of the public health better removed from it.

from Allen, loc. cit., p. 215.

DILATATION OF THE HEART AND OTHER MANIFESTATIONS OF WEAKENING OF THE HEART AS RESULTS OF RHEUMATISM.

BY THEODORE FISHER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS TO THE BRISTOL HOSPITAL FOR SICK CHILDREN; PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

RHEUMATIC dilatation of the heart and rheumatic myocarditis have of recent years been brought more or less prominently before the profession. This has been largely due to the observations of Dr. D. B. Lees and Dr. F. J. Poynton. Dr. Graham Steell also speaks of the injurious effect of rheumatism upon the cardiac muscle and says[1]: "My belief in the importance of the changes wrought by rheumatic endocarditis as the cause of initial incompetence received a rude shock by a post-mortem examination of a patient who had shown the ordinary clinical signs of mitral incompetence from valve lesion. The examination revealed practically sound mitral curtains but a markedly dilated heart." About a year before Dr. Lees and Dr. Poynton brought forward their paper upon dilatation of the heart due to rheumatism I read a paper before the Bristol Medico-Chirurgical Society in which I argued that the generally accepted view of the frequency of mitral regurgitation due to valvular disease had been based upon errors of observation,[2] and used a few clinical facts and others from the post-mortem room in support of my contention. It is scarcely necessary to remark that from the point of view of prognosis the subject is an important one. If a murmur heard at the apex be due to a valvular lesion then there must be few who will maintain that the injury will not be permanent. If, however, the murmur owes its existence to some dilatation of the heart, then there is hope, in some cases at least, that recovery may follow. Dr. Caton,[3] who has noticed cardiac murmurs arising during acute rheumatism disappear under the influence of blisters, mistakes, it seems to me, both the cause of the murmurs and the method of action of his treatment. The patients during the application of the blisters are kept in bed for a long period, and we may suppose that it is not the blisters that cure endocarditis but that prolonged rest in bed enables a dilated heart to contract again.[4] But murmurs may occasionally disappear even after the patient has left the hospital. In 1896 I admitted a girl, aged 10 years, into the Bristol Children's Hospital who was suffering from rheumatic pericarditis. She recovered and a year later she returned as an out-patient for some minor ailment. Although little dilatation of the heart could be detected, a blowing systolic murmur was present at the apex, and the history showed that some weakening of the heart was present. To use her mother's words, "she could not walk up hill as well as her grandmother." At the end of another two years the girl was seen a third time. She had grown considerably and she presented a more animated appearance. In spite of some anæmia, for which she attended the hospital, the dyspnœa on exertion had almost disappeared and no trace of the systolic murmur could be discovered. But rheumatic dilatation of the heart, although it may be uncomplicated by a valvular lesion or by general adhesion of the pericardium, may be permanent and, as the following case shows, may result in early death.

---

[1] The Sphygmograph in Clinical Medicine, p. 35.

[2] THE LANCET, July 18th, 1896, p. 170.

[3] Brit. Med. Jour., vol. i., 1896, p. 207.

[4] It is interesting to note in this connexion that Hibberd observed in 24 cases of diphtheria in which a mitral systolic murmur was present that the murmur disappeared in three weeks in 21 of the cases and in the remaining three in eight weeks. Quoted by Morton Prince American Journal of the Medical Sciences, 1901, vol. cxxi., p. 205.

A youth, aged 19 years, was admitted into the Bristol Royal Infirmary on Nov. 16th, 1899, under the care of Dr. H. Waldo. Two years before he had suffered from an attack of rheumatic fever and did not regain his health after the acute illness had passed away. For three months before admission his strength had been rapidly failing. On admission he was obviously very ill. The cardiac impulse was diffuse and visible as far as the mid-axilla. A high-pitched systolic murmur was audible over the cardiac area and into the axilla and the second sound at the apex was replaced by a "faint rumble." The patient grew worse and was delirious some days before death which took place three weeks after admission. At the necropsy the heart was found to be generally and greatly dilated. It measured across the ventricles just over six inches. Some hypertrophy was also present, as is shown by the weight of 15¼ ounces. A small patch of adhesions about one and a half inches square showed that localised pericarditis had at the time been present over part of the front of the ventricles. Elsewhere the pericardium presented no trace of former pericarditis. The tricuspid and mitral orifices had shared in the general dilatation of the heart. The tricuspid orifice measured six inches in circumference, the mitral nearly five and a half inches. The cusps of the tricuspid valve were normal and neither the flaps of the mitral valve nor the chordæ tendineæ attached to them presented any trace of thickening. The pulmonary valve presented nothing abnormal and the aortic valve was also competent and its cusps were free from thickening. The coronary arteries were healthy and the cardiac muscle to the naked eye showed no fibrosis.

In this case it was impossible to conclude that the small patch of adhesions could have been the cause of the cardiac dilatation. Yet although sufficient damage must have been done to the cardiac muscle to cause death microscopical examination did not reveal any great amount of interstitial myocarditis, much less, in fact, than is not infrequently seen in old-standing cases of mitral stenosis. It seems possible that rheumatism may have the power of interfering with the nutrition of a growing heart and impair the function of the cardiac muscle without giving rise to evidence of very gross lesions. Gross lesions do, however, undoubtedly occur and in the severe rheumatic poisoning which is present in fatal pericarditis the microscope always shows some changes in the myocardium.

It is interesting to note also that in cases where death from pericarditis has been somewhat delayed the presence of disease of the cardiac muscle may often be clearly evident to the naked eye. When the heart has been opened white specks and streaks due to degeneration of the muscle fibres may be seen dotting the heart muscle beneath the endocardium. A similar appearance may occasionally be seen after death from rheumatic heart disease where no pericarditis is present. For example, a boy, 12 years of age, suffering from mitral stenosis, complained of pain in the region of the heart. The pulse became rapid and feeble and four days after the onset of the pain he died. At the necropsy the pericardium was found to be perfectly healthy but the ventricles were speckled with small yellowish-white spots and streaks. On opening the heart the inner surface of the ventricles presented the same appearance in a slighter degree and cuts into the muscular walls showed that the cardiac muscle was everywhere similarly affected.

While, however, lesions of the cardiac muscle may undoubtedly be produced by rheumatism they are not nearly so marked as are those which are frequently present in diphtheria, and it is often difficult to believe that the morbid appearances discoverable by the microscope will explain the cardiac failure which has resulted in death. Yet it must be mentioned that in one case, which I hope shortly to publish, the degeneration of the cardiac muscle fibres in a case of rheumatism was so extreme that it was difficult to understand how the heart could have continued to beat as long as it did. Dr. J. H. Sequeira,[5] noticing the want of evidence of severe damage to the cardiac muscle in some cases of rheumatic pericarditis, has brought forward a theory which he considers explains the dilatation of the heart. It does not appear to me that his theory can be supported by facts but it may be of interest to briefly consider it here. Adopting the views of Hill and Barnard as to the function of the fibrous pericardium Sequeira[6] considers that when inflamed it becomes weakened and fails to exert efficiently its power of preventing abnormal distension of the heart. It is doubtful, however, whether the inflammation of the serous pericardium affects the fibrous pericardium so seriously as to cause it to give way readily under pressure. In more severe forms of pericarditis, such as the suppurative pericarditis of pneumonia, where one would expect the fibrous pericardium to be more affected, the dilatation of the heart is not nearly so marked as in rheumatic pericarditis.[7] But on other grounds we may consider Dr. Sequeira's theory to be highly improbable. A few simple experiments in the post-mortem room will show that if the pericardium exerts a restraining power upon distension of the heart it must do so only in extreme emergencies and it is doubtful whether it can exert any pressure upon the heart even then. The method of showing this is as follows. After rigor mortis of the heart has passed off the pericardium is distended with water at a certain pressure—e.g., that of a column of water 10 inches in height. A measure is taken of the number of ounces of water used. After tying the vessels of the heart at their points of entrance into, and exit from, the pericardium this membranous sac is cut open and the cavities of the heart are distended at the same pressure as that employed in filling the pericardium. The amount of water required is noted, the heart is opened, and a measure is taken of the amount of blood-clot which it contains. The number of ounces of water used in filling the heart, together with the blood clot which it may contain, will almost invariably be found to be less than the amount of water held by the pericardium. A few examples may be given. In the case of a man, aged 24 years, who died from enteric fever, the pericardium held 20 ounces of water, and the four cavities of the heart 14 ounces of water and blood-clot; in that of a boy, aged 14 years, who died from enteric fever, the pericardium contained 15¼ ounces, and the cavities of the heart nine and a half ounces; in that of a man, aged 21 years, who died from enteric fever, the pericardium held 20 ounces, and the heart 15¼ ounces; in that of a youth, aged 18 years, who died from enteric fever, the pericardium held 12 ounces and the heart 11 ounces; in that of a man, aged 60 years, who died from carcinoma of the stomach, the pericardium held 18 ounces and the heart 12¼ ounces; and in that of a woman, aged 39 years, who died from cirrhosis of the liver, the pericardium held 18 ounces and the heart 13¼ ounces. In one instance, however, in which the heart was apparently healthy, the cardiac cavities contained more than had been held by the pericardium. In the case of a woman who died from suppurative peritonitis consequent upon perforation of a gastric ulcer the pericardium held only 15 ounces while the heart held 22 ounces. In another case where the heart was greatly dilated owing to the presence of fibrous myocarditis the pericardium held 24 ounces but the heart held 30 ounces. In the last case, however, it is worthy of note that the cardiac muscle was diseased and consequently the fact that the heart was capable of holding more water than the pericardium shows that the pericardium was unable to prevent the dilatation of the heart which resulted from this disease. This case, therefore, tends to militate against, rather than to support, the theory that the pericardium can exert a restraining influence upon dilatation of the heart. But allowing that in some instances a healthy heart can be distended in the post-mortem room more than the pericardium it is very doubtful whether that would be possible during life. All four cavities could not then be fully distended at the same time. There must be room within the pericardial sac for the auricles to empty themselves into the ventricles.

It would appear, then, that in most people the fibrous pericardium does not fit the heart so closely that there is not sufficient space within it for considerable dilatation of the heart. If this be so we may dismiss from our minds the idea that the dilatation of the heart which occurs in rheumatic pericarditis is simply due to weakening of the fibrous pericardium. Although microscopical examination of the cardiac muscle may not reveal the amount of disease one might expect, the most reasonable explanation of the dilatation is poisoning of the heart-wall.

---

[5] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxii., p. 360.

[6] Ibid., p. 410.

[7] A recent paper by Dr. Still shows that the absence of marked dilatation of the heart in the pericarditis of pneumonia has attracted his attention. Brit. Med. Jour., vol. ii., 1901, p. 606.

Rheumatic poisoning of the heart does not, however, occasion only dilatation. After rheumatic pericarditis some hypertrophy usually takes place and may be great in degree. This has been attributed to the deleterious effect of adhesions, but occasionally one may meet with enlargement of the heart following a rheumatic attack in which neither adhesions nor valvular disease are present. For example, a boy, aged eight years, was admitted under the care of Dr. S. W. Wheaton into the Royal Hospital for Children and Women, Waterloo-road, in 1892, who had suffered for two years from symptoms pointing to disease of the heart. A few weeks before admission these symptoms had become aggravated at a time swelling of the knees had been present. On admission there were great dyspnœa and a rapidly beating heart, the pulse being 140 to the minute. The dyspnœa became worse and the pulse more rapid and at the end of 10 days the boy died. At the necropsy no trace of pericarditis could be found. The heart was much enlarged, extending downwards to the sixth intercostal space and outwards one inch to the left of the nipple line. Its weight was 10 ounces, double the normal weight for a boy of his age. A previous attack of rheumatism was indicated by thickening of the segments of the aortic and mitral valves and a recent attack by rows of small vegetations upon the same valves. The aortic valve, however, was competent and it was obvious that the thickening of the mitral valve could account neither for death nor for the great enlargement of the heart. Clinically the symptoms were those of pericarditis and it seemed reasonable to suppose that death had been due to rheumatic poisoning of the heart-muscle without the usual association of inflammation of the pericardium. Microscopical sections of the heart-wall seemed to show that the enlargement was in part at least of recent origin, since in addition to some interstitial myocarditis the blood-vessels were greatly injected. In this case apparently the enlargement was mainly, but by no means entirely, due to increase in the amount of blood in the heart-wall. That a great quantity of blood and serous fluid in the heart-wall may be partly responsible for enlargement of the heart in rheumatic pericarditis is suggested by the rapidity with which the weight of the heart may increase. Dr. Goodhart long ago noticed this rapid enlargement in rheumatic pericarditis and he showed a specimen before the Pathological Society of London from a youth, aged 17 years, where the heart apparently doubled its weight in a month.[8] Dr. Sequeira mentions a case where, in a girl, aged 11 years, it doubled its weight in three weeks, and I have met with an instance where the heart apparently increased in size to the same amount in a fortnight. A girl, aged 11 years, was admitted by me into the Bristol Children's Hospital for rheumatism with rheumatoid nodules. I could detect no enlargement of the heart. Three weeks later acute pericarditis set in and after it had lasted a fortnight the girl died. The heart was found to weigh 11½ ounces, fully double the normal weight in a girl of her age. There was recent endocarditis but no old disease of the valves. On microscopical examination the sections showed an unusual amount of interstitial myocarditis associated with great injection of the blood-vessels. In some sections the distended capillaries occupied nearly as much space in the field as the muscular fibres. This injection of the blood-vessels, in varying degree, is a constant feature of microscopical sections of the heart-muscle from cases of rheumatic pericarditis. The appearance of the interstitial tissue frequently suggests also that an increase of serous fluid in the heart-wall is present. It is possible, however, that enlargement of the heart may be in part due to increase in size of the muscle fibres. In their weakened condition they may attempt to gather fresh energy by calling more largely upon their sources of nourishment and swell up in so doing. Although the enlargement of the heart which occurs in rheumatic pericarditis may be of this comparatively simple nature it must be noted that it does not often subside when the acute inflammation has passed off. On the contrary, the hypertrophy may go on increasing until the heart even of a child of the age of 12 years may weigh between 20 and 30 ounces. Dr. J. F. H. Broadbent has suggested that when the heart is dilated adhesions resulting from the pericarditis prevent its return to the normal size. Adhesions, however, do little to hamper the action of the heart, as is shown by the fact that when they follow pericarditis due to other causes than rheumatism, such as pneumonia or tuberculosis, no enlargement of the heart takes place.[9] The only way in which pericardial adhesions could retain the heart in its dilated condition would be through the médium of other adhesions outside the fibrous pericardium provided on all sides with fixed points of attachment. Such fixed points, it is needless to say, cannot be found. The chest-wall provides in front an area of attachment, but adhesions when present there are generally of too loose a character to be capable of preventing movement of the heart. The mobility of the heart, it may be remarked, in cases of enlargement following pericarditis, can in some cases at least be proved clinically by noting the different positions of the apex-beat when the patient is lying in the recumbent position and upon the side. It has not been my custom to test this point in every case, but in three cases of enlargement of the heart following acute rheumatic pericarditis in which the position of the apex-beat in different positions of the body has been noted I find that movement occurred in every instance. Thus, in a girl, aged 12 years, who was examined before her return home after an attack of pericarditis, the apex-beat when she was lying on her left side was fully one inch to the left of the position which it occupied when she was standing up. It may be added that the girl returned six months later and died. The pericardium was found to be universally adherent by loose adhesions. Although the heart had been freely moveable it was much hypertrophied. The weight was 14 ounces.

The above facts—namely, that adhesions left by pericarditis due to such diseases as pneumonia or tuberculosis do not lead to hypertrophy of the heart, and that the heart may be freely moveable over the front of the chest-wall and yet continue to increase in size—show that neither internal nor external pericardial adhesions can be the cause of cardiac enlargement following rheumatism. To offer a better explanation is, however, not easy. Yet it seems possible that poisoning of the cardiac muscle may interfere with its nutrition and occasion hypertrophy. The power which poisoning of the heart-muscle possesses to give rise to enlargement of the heart is seen in the hypertrophy due to over-indulgence in alcohol. It may be mentioned in passing also that it seems possible that the enlargement of the heart attributed to exercise and work may also be due to poisoning of the cardiac muscle by waste products of metabolism. Such enlargement appears to occur, not where there is hard work merely, but where hard work and exposure to great heat are combined. The only two cases of enlargement of the heart which I have met with in the post-mortem room of the Bristol Royal Infirmary which could be attributed alone to the strain of excessive work occurred in a blacksmith and in a stoker in gas-works. Perusal of the Guy's Hospital post-mortem records for 10 years showed three cases which by exclusion of other causes seemed to resolve themselves into hypertrophy due to overwork. These three cases occurred in a blacksmith, a stoker, and a labourer in gas-works. Possibly work in great heat causes the water drunk to be thrown off almost entirely by the skin and leads to the retention in the circulation of waste products of metabolism which would otherwise be excreted by the kidneys. The waste products weaken the heart which in attempts to carry on its work occasions its own hypertrophy.

To return, however, to enlargement of the heart due to rheumatism, if a poison such as alcohol can produce enlargement of the heart it does not seem unreasonable to suppose that the toxins of rheumatism may do so also. This appears especially probable when it is remembered that rheumatism affects the heart most seriously while that organ is growing. Marked enlargement of the heart very rarely follows an attack of rheumatic pericarditis occurring after the age of 20 years. An altered nutrition due to poisoning of the cardiac muscle would explain also the weak nature of the hypertrophy. Some statistics[10] gathered by me from the Guy's Hospital post-mortem records illustrate this weakness. They show that rheumatic pericarditis occurring before the age of 12 years and followed by enlargement of the heart generally leads to death before the age of 20 years and very frequently about the age of 15 years. Thus the records during seven years showed 13 cases of death at the age of 15 years and under in which enlargement of the heart was associated with general adhesion of the pericardium but without marked valvular disease. In six of these the valves were described as being normal. As an example of the enlargement of the heart in these cases in the absence of associated valvular disease it may be mentioned that in a boy, aged 13 years, the heart weighed 22 ounces. Four cases of death occurred between the ages of 15 and 20 years, but in these cases valvular disease was more marked, and after the age of 20 years there was no case of enlargement of the heart associated with general adhesion of the pericardium in which the valvular disease was so slight that its importance as a cause of death could be excluded. Death may not occur until after the age of 20 years, but if much hypertrophy of the heart be present death will not be long delayed. A case now and again may be met with where the cause of death is an enlarged heart associated with general adhesion of the pericardium without marked valvular disease, as late as the age of 25 years, but I have never met with one after that age. An adherent pericardium may be found to be present in cases of death from rheumatic valvular disease at almost any age, but in later life unless aortic regurgition be present the cardiac hypertrophy is rarely great. Sequeira,[12] who has comparatively recently carefully investigated the question of prognosis after pericarditis, gives extensive statistics which point to similar conclusions, but the additional fact is brought out that the fatality of enlargement of the heart associated with general adhesions of the pericardium is much greater about the age of 15 years in girls than it is in boys.

---

[8] Transactions of the Pathological Society of London, 1879, p. 279

[9] This is possibly not absolutely true. I have met with two cases in which dilatation of the heart appeared to have been the sequel of pericarditis in pneumonia. Such cases, however, in my experience are very exceptional.

[10] Adherent Pericardium in Children, Bristol Medico-Chirurgical Journal, 1894, p. 93.

Pericarditis is an evidence of the most acute form of rheumatic poisoning of the heart and consequently the results are generally serious, but other minor manifestations of weakening of the heart may follow less severe poisoning by rheumatism. Although after a child has suffered from rheumatism no enlargement of the heart and no murmurs may be evident, the parents may complain that the child has lost its energy and that it is perhaps subject to fainting attacks, possibly when standing in school. Even mild attacks of angina pectoris may be present. Such attacks are thought to be due to hysteria, but it is possible for a neurotic disposition to mislead by causing an exaggeration of symptoms which have a physical basis. We know that the fatal form of angina pectoris is generally due to serious disease of the cardiac muscle and it seems reasonable to think it probable that many of the milder varieties of cardiac pain are due to slight disease or to temporary disturbance of nutrition of the myocardium.

Another interesting sequel of rheumatism in children is tachycardia. A brief reference to a mild case may be of interest. A girl, aged four years, was brought to the Bristol Children's Hospital by her mother who stated that the child often turned pale, complained of pain over the region of the heart, and that on putting her hand to the chest the mother could feel the heart beating forcibly and at a great rate. Physical examination of the heart revealed nothing noteworthy. It was, however, beating rapidly—148 to the minute. There was a history of pain and swelling in the joints and, curiously enough, during the week after the first visit to the hospital the child had to be kept in bed owing to pain and swelling in the right knee. In another case the heart of a boy, aged eight years, who had suffered from rheumatism was said to beat occasionally "as fast as it could beat." Few necropsies have been made upon cases of tachycardia but the heart-muscle has been found diseased in three out of six cases, a fact which suggests that when attacks of rapidity of the pulse follow rheumatism they are an indication of weakening of the myocardium.[13]

Various points in connexion with disease of the cardiac muscle following rheumatism have been briefly dealt with. To summarise a few, they are first, that dilatation of the heart ending in death may occasionally occur without valvular disease or general adhesion of the pericardium being present; secondly, that in rare instances hypertrophy of the heart may occur without valvular disease or general adhesion of the pericardium; thirdly, that there is evidence that myocarditis may exist in the absence of pericarditis; and fourthly, that slight weakening of the myocardium may be shown by loss of physical energy, by attacks of cardiac pain, or by tachycardia.

The causation of dilatation and of hypertrophy of the heart associated with rheumatic pericarditis or with general adhesion of the pericardium has been considered and it has been thought that the most reasonable explanation of both is poisoning of the cardiac muscle.

Bristol.

THE VENTILATION OF SHIPS, WITH A DESCRIPTION OF AN EFFICACIOUS METHOD

BY WILLIAM EDWARD HOME, M.D., B.Sc.,
M.R.C.P. EDIN.,
STAFF-SURGEON, R.N.

Now that scurvy has almost disappeared the chief cause of unhealthiness on board ships is overcrowding. Everyone who has read the report of the Plague Commission knows overcrowding to be, in the words of the president, Professor T. R. Fraser, "a relative term, and not co-relative with any specific number, but with the number present in a given space and the efficiency of the ventilation of that space."[1] Anything, then, that improves the ventilation of ships is of the greatest importance to us who practise at sea and to those in ships, passengers or crew, whose health is trusted to our care.

To secure adequate ventilation afloat is generally a struggle, except in a small craft in the tropics in fine weather. In bad weather it is almost impossible in an ordinary ship to get any ventilation at all, it is so difficult to exclude water from the pipes and openings intended to convey air only, and water must be kept out even if air has to be excluded also.

I am sorry to say that it was only recently that I came across a now widely used system of ventilators which has overcome this difficulty and which supplies a little fresh air during any weather. It was devised by Mr. Thomas Utley of Liverpool and has long been used in the largest ships in the world driving through the wildest weather, but I have not hitherto seen it described in the medical press.

Now, water troubles us in two separate forms—as rain, in comparatively small quantity, or in the great volume of seas swooping past, and each form has to be met differently. Rain, of course, gives less trouble and it is excluded in the Utley skylight ventilator by an obvious arrangement of louvres and baffle-plates in the ridge of the skylight. Something of the same sort is done in Boyle's inlet ventilator. But the most novel and ingenious of these patents are those which exclude sea-water in mass. In each of the ventilating passages are two valve chambers containing cork floats of similar size (five inches in diameter and two and a quarter inches thick for a 12½ inch scuttle) travelling up and down on a central spindle. These valves, when air only passes, remain in their position of rest with the gangway left clear, but should a sea strike the ventilator and try to pass the valves first the lower, or distal, float, which is very loose on the spindle, is floated up and jammed against the concave top of the chamber, the joint being secured by a flexible disc of red rubber with thin tapering edges so arranged that the greater the pressure of the sea the more firmly is the rubber approximated to the roof of the chamber. A little water is forced through centrally and that in the same way, if in sufficient volume to be troublesome, seals the proximal chamber and thus no water passes the valves. Between the seas the cork valves fall back as the water drains away and the passage for air is again established.

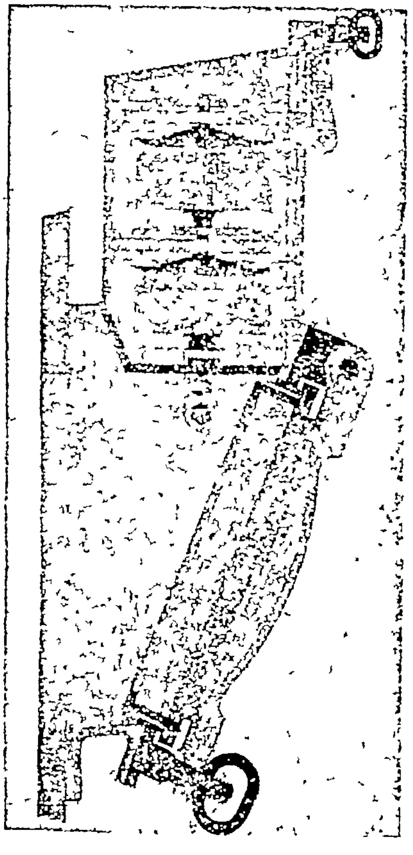
The Utley porthole ventilator is shown in section in the accompanying illustration. It replaces the ordinary round "ports," "sidelights," or, as we call them in the navy, "scuttles." In its best form it takes up rather more room inboard (a matter of very little importance in a ship with a lining), slightly diminishes the amount of light, and costs about twice as much as the ordinary scuttle, but in consequence of the improvement which it works in the hygiene and amenity of the ship it is extensively used. I saw it in the *Oceanic* and in the

---

[1] Report of the Commission on Plague, vol. v., Appendix III., p. 477.

Cymrio, and I am told that every scuttle is so fitted in the *Lucania* and in the *Campania*—a sufficient proof that the system can withstand the heaviest weather. In case of fire the ventilating passages can be closed by plates analogous to deadlights.

I think that this system may be of great service to us in the navy, particularly as we are now giving up the ventilating of ships by cowls which will splinter in action if struck, but so far the Utley patent porthole ventilator has only been fitted in His Majesty's new yacht which had 146 built into her. Everyone will at once recognise that great benefits accrue to passengers in bad weather if such a ventilator is used, not only in preventing the ordinary results of overcrowding, sore-throats, boils, &c. (even typhus fever, that cousin german to plague, has broken out in crowded and ill-ventilated transports), but also in diminishing the evil effects commonly ascribed to sea-sickness, many of which, indeed, are due to bad weather only because it prevents any ventilation of the cabin to which the patient confines himself. And who is there, however good a sailor, who could live for two or three days, and, perhaps, with one or two companions, in a cubic space of 300 feet without much ventilation and not lose appetite or be otherwise "capsized"? We have all the apparently greater need for ventilation at sea as our standard of cubic space is 100 feet where that ashore is 1000 feet, even if we can do with less than 3000 cubic feet an hour of fine, fresh sea air with all its ozone



The illustration shows the Utley porthole ventilator in section. It is represented closed up as it would be in case of fire and, of course, not working. To the reader's left is the sea, the vertical line to the left is the ship's side; the inclined part to the right is the glass light covered by its protecting "dead light"; at the upper part the ventilating passages are seen arranged tandem, each with its large block of cork forming the valve. To allow the ventilator to act the handled screw shown at the top must be eased and turned up, when the iron plate covering the air passage can be dropped down.

There is an Utley cowl and deck ventilator, too, in which the double valves are fitted in cages (four, six, or eight) on the sides of the air-shafts. These cowls are made of steel and have a cap fitted like a deadlight that can be secured over the mouth. When this is closed in bad weather ventilation is not entirely stopped but some air can still pass safely either out or in—a great improvement on the old method which in bad weather replaced the cowl by an impermeable deck-plate.

The commercial value of these ventilators is shown in their use by the White Star, the Cunard, the Peninsular and Oriental, the Dominion, the Hamburg-American, the North German Lloyd, and other companies, and by our own and the German Governments.

Perhaps some medical officers of ships fitted with these ventilators will tell the readers of The Lancet if they have diminished sickness; particularly would it be of interest if anyone could give his experience of two voyages to South Africa in transports equally full of men, one with these ventilators and one without.

H.M.S. *Galatea*, Chatham.

DIFFICULTIES IN DIAGNOSIS: CHICKEN-POX OR SMALL-POX?

By W. M. YOUNG, M.D. R.U.I.

A waitress in a City restaurant, 22 years of age, felt so ill on April 26th that she left her employment about the middle of the day, returned to rooms occupied by her sister in a house in Paddington, and there took to bed. When I saw her in the course of the afternoon she presented all the characteristics of a rather severe bout of the "rheumatic" variety of influenza. During the febrile stage she was treated with salicylate of sodium combined with ammonia, paregoric, and extract of liquorice. On the 29th, defervescence having been accomplished, she was given a mixture consisting of half a drachm of sulphate of quinine, half a drachm of solution of strychnine, two drachms of dilute hydrobromic acid, and compound infusion of gentian to six ounces, one tablespoonful to be taken three times a day in water. My next visit took place on the afternoon of May 1st and she then informed me that, as the catamenia had appeared during the previous night and she had not felt quite so well, she had remained in bed during the day. I noticed a few papules on her face but I looked upon these as associated with the menstrual period and possibly intensified, if not actually brought out, by the administration of the hydrobromic acid in the mixture. I did not think it worth while to use the thermometer as there was nothing to suggest a rise in the temperature and all the indications seemed to point to a mere evanescent menstrual disturbance. On the morning of the 2nd, however, I received a message requesting me to call to see the patient during the day and I accordingly paid a visit early that afternoon. The papular eruption had then become so prominent on the face as to be actually disfiguring and it had also appeared rather profusely at the back of both wrists. The temperature was 102° F. There was considerable discomfort in the lumbar region. The patient looked exceedingly ill and evinced such a decided tendency to syncope that strychnine was administered hypodermically. On the morning of the 3rd a large crop of papules appeared on the back of the neck and shoulders. The temperature had fallen to 101°. The other symptoms, including the severe prostration, were much the same as before and the patches of eruption which had first appeared still remained in the papular stage. On the morning of the 4th things remained much the same with the exception that the eruption had taken on a vesicular form. During the day the vesicles matured so rapidly that I came to the comforting conclusion that, notwithstanding the course followed by the eruption and the severity of the general symptoms, the case was nevertheless one of chicken-pox. My self-congratulations at having steered clear of the dread Scylla of premature removal of the patient to the small-pox hospital were, however, chastened by finding myself involved immediately afterwards in the vortex of a veritable Charybdis. The pronouncement to which I had committed myself in favour of the existence of the minor disease brought upon me a visit at my own residence from the occupier of one-half of the house in which the patient was lying. My uninvited visitor was so minatory in his attitude and seemed so anxious to assume the airs of a sea-lawyer in his cross-examination of the evidence on which I had based my diagnosis that I deemed it advisable to obtain a second opinion in order to protect myself against eventualities As it was Sunday I did not care to bother the medical officer of health so I asked a friend in the neighbourhood to see the case.

with me. The latter, whilst admitting the perplexing character of some of the symptoms, concurred in the diagnosis of varicella. The reception of the certificate by the medical officer of health on the following morning led to a friendly call from Dr. R. Dudfield during the afternoon. He was so much impressed by the resemblance which my description of the onset and development of the eruption bore to a case of modified small-pox, and a day or two previously he had been rendered so suspicious of such cases by having had what proved to be the more serious disease notified as the milder complaint, that we agreed that it would be best to visit the patient together. Even at this late stage the case was not at all one for "lightning diagnosis" and it was only after some considerable examination and discussion that the necessary official confirmation was given, the correctness of which has since been completely verified.

The case had a twofold interest: It was a good object-lesson in the pitfalls ever liable to trip up the cocksure tyro who refuses to apply to himself the sententious maxim of the late Master of Trinity "We are none of us, not even the youngest, quite infallible." It also threw an interesting sidelight on what some people are pleased to call the frame of mind which is connoted by the fad of anti-vaccination. In the first instance the papular eruption bore a marked resemblance to a manifestation of bromism If some little rise of temperature had been detected at this stage it might have been attributed fairly enough to the onset of the menstrual period so soon after the subsidence of the attack of influenza. The same conjunction of causes doubtless did occasion the discomfort in the lumbar region, which although not amounting to actual pain in the back was sufficiently pronounced to be credited with a note of interrogation. The adult age of the patient, the appearance of the eruption first on the face and wrists, the prolonged papular stage of the earlier patches, the fall in the temperature at such an early stage of the development of the eruption, and the apparently profound constitutional disturbance all seemed to betoken varioloid. On the other hand there was never any vomiting or even nausea, there was very little headache, and later, when the papules had become vesicles, they matured so rapidly as to furnish the clue to a correct diagnosis.

The profound prostration which was a feature of the early stage and which lasted until the definite diagnosis had been established was a confusing but interesting incident, a fraction of it might properly be set down to the renewed febrile condition supervening on the debility which was the inevitable sequel of the influenza. By far the larger proportion of the disturbing influence was, however, not physical at all but psychic. The phenomenon was, in fact, "a sort of" death-bed repentance. A short time previously the girl, in common with the other members of the staff of the restaurant, had been given the opportunity of being vaccinated. Some propagandist of the anti-vaccination cult had, however, plied her with blood-curdling descriptions of the horrors attendant upon vaccination, with the result that she had declined to submit to the operation Still she had "had her doubts" about the soundness of the advice which had been given to her and when the eruption appeared copiously on her face on the morning of May 2nd her appeals as to whether it was small-pox and whether she would be much marked were quite piteous. The rather aggressive officiousness of the fellow-occupier of the house was to all intents and purposes a like exhibition of "the doubt of doubt." This gentleman first of all informed me in dogmatic fashion that he "did not believe in vaccination." Having thus duly paid obeisance to his fetish, he went on in more subdued tones to say how much he had been disturbed by the thought of his wife and children being possibly exposed to the contagion of small pox At last he confessed that his anxiety had become so great that he was contemplating, as a lesser evil, the handing over of them all to the cruel tender mercies of that modern personification of "the wicked," yclept ye public vaccinator

In a general way the revelation of the Falstaffian character of the courage of the anti vaccinationist has been one of the most salient features of the recent scare. During the years of immunity from the disease the Superior Person who (to quote the autobiographical notice of an orating anti vaccinationist in "Who's Who") "has not been educated at all academically" achieves a certain measure of cheap notoriety by the vulgar flippancy of his references to the opinions of men of education who have devoted their lives to the investigation of the prevention of disease. Notwithstanding his "brave words" under such circumstances the attitude of the anti-vaccinationist in the presence of epidemic danger is often that of the stock character of Goody-goody story who, having duly shocked his maiden aunts by the blatancy of his atheism, is unexpectedly brought to the very verge of the Stygian river and there awakens to the terrible conviction that there may be a particularly sultry climate on the other bank after all

Pembridge-road, W

PRIMARY GANGRENE OF THE TONSILS.

By ROBERT FULLERTON, M D EDIN,
SURGEON TO THE OUT-DOOR DEPARTMENT FOR DISEASES OF THE THROAT
AND NOSE OF THE ROYAL INFIRMARY, AND LECTURER IN
ST MUNGO'S COLLEGE, GLASGOW.

THE throat condition which forms the subject of the following notes occurred in the case of a medical friend, aged 37 years, who consulted me on June 13th, 1900 The history given stated that during the spring months he had become very much run down in health, was easily tired, and, indeed, felt so weak that he was scarcely able to carry on the duties of his practice. About the middle of May a severe cold in the head, which was accompanied by a considerable amount of nasal discharge with pain in both ears and in the pharyngeal region, confined him to the house for a week. The tonsils were not appreciably affected at this time, but about a week after resuming work they rapidly and without any apparent cause became acutely inflamed and the temperature rose to 103° F Four days after this onset the throat presented the appearance of an acute follicular tonsillitis. About a week later an ulcer was observed on the right side of the upper lip, not far from the angle of the mouth A few days afterwards a slough appeared on each tonsil. These sloughs spread rapidly and with this extension the parts became extremely painful

When seen by me the patient, although usually robust, looked pale, anxious, and very ill. The throat was so acutely painful that the act of swallowing was rendered almost impossible. He spoke with difficulty and the voice was muffled and markedly nasal. The tongue was thickly coated, shreds of secretion clung to the palate, and the odour from the mouth was heavy and fœtid. The lymphatic glands at the angle of the jaw on both sides, but more especially on the left, were enlarged and tender to touch. The faucial tissues generally were inflamed and swollen and the uvula was markedly œdematous. A shallow ulcerated patch of about the size of a small lentil was present on the right upper lip, the edges of which were irregular but clean-cut, whilst the base when not covered by a yellowish débris had a raw look. The swollen tonsils—elongated and sessile in type—were covered in front by an adherent portion of the anterior pillars of the fauces. A sinuous trench-shaped excavation was present in the left tonsil, extending downwards to almost its lower limit from immediately below the edge of the soft palate. A greenish-yellow slough occupied this cavity which at the upper part appeared to involve the whole depth of the tonsillar tissue but became more superficial at its lower extremity On removal of the slough the edges were found to be indurated and raw looking A small croupous patch, which was easily wiped off, was present on the surface of the tonsil. (See illustration.) The slough on the right tonsil, though not so extensive, closely resembled that just described. Neither the epiglottis nor the larynx was involved, and although a post rhinoscopic view could not be obtained the inflammation appeared to be confined to the tissues of the fauces

The appearance of the throat differed from anything that I had hitherto observed and conveyed the impression of a tertiary specific affection in a pharynx acutely inflamed. There were, however, no grounds for attributing it to syphilis and the history and subsequent course of the disease are against its having been due to that.

Prior to the patient being seen by me iron and quinine had been taken internally and antiseptic paints and gargles had been applied locally with little or no effect. I applied a 10 per cent. solution of cocaine to the parts and having removed as far as possible all the necrotic tissue and débris, swabbed the ulcerated surfaces with a strong solution of carbolic acid. In addition to having the mouth frequently washed out he was directed to take four times a day without dilution a teaspoonful of a mixture of tincture of the perchloride of iron and glycerine, one drachm to one ounce. When seen three days later the parts had much the same appearance as at the first examination, but the necrotic shreds having been then removed the cavities were now easily cleaned, and a solution of nitrate of silver (one drachm to one ounce) was applied to the raw surfaces. The treatment prescribed was the iron and glycerine mixture with a grain of opium at night and swabbing the ulcers twice daily with a 1 in 20 carbolic acid solution. The patient, who in the meantime had been living at a sheep farm in the country for a fortnight, called again on July 19th. He stated that upon removing from town the parts had gradually healed and had remained well for a week, when the upper part of the left scar broke down. To this I applied the electric cautery and it healed in a few days. For several months subsequently the general health was indifferent but the throat gave no further trouble. When seen quite recently the site of the sloughs was marked by a distinct loss of tissue but there was no trace of the ulceration which had been present on the lip.

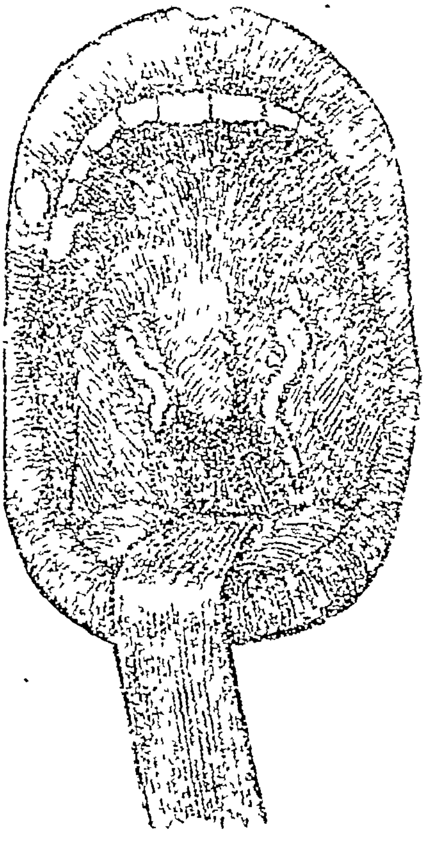


Figure to illustrate the fauces in Case 1. The gap in the outline of the upper lip is a fault in the drawing.

I felt a little uncertain as to the classification of this case and although it differed essentially from the acute ulcerating lacunar tonsillitis described by Moure, four examples of which I had seen, I was at first inclined to regard it as an unusually severe form of this affection.

About five months later—on Nov. 2nd, 1900—Dr. Alexander Robertson sent one of his servants to consult me in regard to a sore-throat from which she suffered. The girl, who was 23 years of age, stated that about four weeks previously she had caught cold when her tonsils became inflamed and had remained uncomfortable ever since. Three days before seeing me the right tonsil became very painful and the glands of the neck began to swell. The patient looked ill and complained of great pain on the right side of the throat. The lymphatic glands behind the angle of the jaw on the same side were considerably enlarged and very tender to touch. A slough in position, shape, and general characters identical with, although not so extensive as, that just described, was present on the right tonsil and the patient stated that it had appeared only that day. The left tonsil was inflamed but the surrounding tissues were not affected by the inflammatory action to any marked extent. The patient was sent back with directions as to treatment, but the condition becoming rapidly worse she was admitted into the Royal Infirmary under Dr. John Macintyre. From notes which Dr. Macintyre has kindly furnished I am enabled to indicate briefly the further course of the case.

On admission her fauces were much congested and a deep ulcer covered by a whitish exudation was present on each tonsil. The throat was painful and the glands of the neck were enlarged. The patient remained in the hospital on this occasion for four months. The treatment consisted at first in the administration of iron with antiseptic applications locally. After this a course of anti-specific remedies was carried out followed by tonics. Repeated bacteriological examinations of swabbings from its ulcerated surfaces were made. The first of these revealed the presence of staphylococcus and diplococcus and on examination a fortnight later the pneumococcus was found in an almost pure culture. These were the only forms of micro organisms noted as having been found and at no time during this period could either the diphtheritic or the tuberculous bacillus be found, although six weeks after admission slight consolidation was detected at the apex of the right lung. In spite of all that could be done the ulceration spread on both sides, affecting the soft palate and the uvula.

At the end of February, 1901, four months after admission, the ulcerative process was arrested and the patient left for her home. She was readmitted on Oct 21st, 1901, nearly a year after the first onset. It was now found that food regurgitated to some extent through the nose; the posterior pharyngeal wall, the back of the naso-pharynx, the tonsils, the posterior pillars, and part of the anterior pillars of the fauces were all involved and denuded of their mucous membrane and the soft palate had largely disappeared. The tubercle bacillus was now found in the sputum. The patient died on Nov. 29th and the post-mortem examination showed that the larynx and trachea were healthy, that the left lung was adherent from tuberculous pleurisy, and that both lungs had excavations of their upper lobes and that the other lobes showed a tuberculous pneumonic infiltration.

The occurrence of the second case, so closely resembling in its local characters the first but so different in its ultimate course, naturally led me to reconsider my diagnosis in the first, and I concluded that both were illustrations of a primary gangrenous process in the tonsils. In support of this view I would refer to the report of Brindel and Raoult on Ulcerations of the Tonsil.[1] Here, under the heading of *Grangrene of the Tonsil*, a case seen by Brindel is quoted, the course of which, up to the time of death from a severe hæmorrhage, seems to have closely resembled the second of those which I have just noted.

From a diagnostic point of view the picture which they presented might well have been confounded with that of a tertiary specific lesion. In both instances, although the causes and processes are somewhat different, the result is the same—viz, a localised gangrene of the tissues involved. In differentiating this affection from syphilis the history of a specific infection and the fact that tertiary ulcerations of the pharynx usually begin on the soft palate or the posterior pharyngeal wall would assist in forming a decision which would be confirmed or otherwise by the result of anti-specific treatment

When a diagnosis of primary gangrene is made the treatment adopted ought to be prompt and energetic. Iron and quinine should be administered and opium should be given freely. Locally, after cleansing the parts the electric cautery should be thoroughly applied to the ulcerated surfaces.

These cases are interesting, pointing as they do to the tonsils being a likely site for microbic infection which may set up lesions of a serious nature, and especially in those in in whom the powers of resistance are weakened. In regard to the study of such acute septic inflammations of the throat Sir Felix Semon did good service when he argued for their pathological identity.[2] There may be, and probably are, factors we know nothing of which determine the type of the pathological process, be it gangrene, erysipelas, œdema, &c.,

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF TABES MESENTERICA WITH INTENSE PIGMENTATION OF THE SKIN

By WALKER OVEREND, M.A., M.D. OXON.,

LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL.

THE patient was a girl, aged two and a half years, who began to suffer at the end of 1901 from a severe attack of pertussis. During the progress of the disease abdominal tuberculosis gradually developed. In the middle of January, 1902, the abdomen was thin, flaccid, and deeply pigmented. On palpation a lump was readily felt just inside the left external iliac spine and a smaller one a little higher up in the neighbourhood of the left kidney, close to the spine. There was neither liver dulness nor ascites and the lungs were normal. Pigmentation was distributed over a large part of the body but most deeply over the left side of the abdomen. Above it reached to the level of the nipples and then faded off towards the neck. This discolouration was almost symmetrical. It existed along the front and inner aspect of each thigh and leg as far down as the ankle. On the back the bronzing formed a zone reaching from the eighth dorsal spine to the level of the head of the femur. The axillæ were pigmented and an area of discolouration extended along the inner side of each arm as far as the elbow. The prognosis appeared exceedingly grave but now after an interval of four months the pigmentation has faded until it is almost imperceptible and the lumps have disappeared. There is still, however, a doughy feeling in the abdomen and the little girl continues exceedingly thin in spite of a ravenous appetite.

The bronzing was apparently due to the pressure of enlarged mesenteric glands on the left suprarenal body. A similar instance is recorded[1] where after death enlarged glands were found pressing upon the left suprarenal body without involving its structural integrity.

Clacton-on-Sea.

ACUTE DERMATITIS CAUSED BY COTONEASTER MICROPHYLLA.

By HARRY J. COOPER, M.A., M.B. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE CLINICAL ASSISTANT IN THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS AND IN THE SKIN DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE following cases seem to me to be worthy of publication as I can find none on record due to poisoning by *Cotoneaster microphylla*, in addition to which the plant is a common one in gardens, but probably not usually so extensively grown as in the grounds from which the cases in question emanated. In these grounds there is a pergola over a 100 yards in length covered by this plant, besides some low walls over which it is grown. This extensive growth of the plant necessitates care from time to time in the way of clipping. In two of the cases now under notice the patients came to me at the same time just after one of these clippings.

CASE 1.—On Dec. 17th, 1897, a gardener, aged 33 years came to me with a raised patch on his right wrist, rather larger than a five shilling piece, the edges having an urticarial appearance, the centre of the patch was covered with exuding points; in addition there was an erythematous condition of the forehead with papules on the hands and thighs accompanied with much irritation. On the 19th the original patch on the wrist was four inches across and was still raised with a white areola surrounded by a red one, some of the exuding points had by this time become scabbed over. The papules on the thighs were now more urticarial in appearance; the eyelids and forehead much swollen. The man's tongue was clean, his pulse rate was 72, and his temperature was normal. These symptoms gradually subsided and he was practically well in 10 days.

CASE 2.—I saw the second patient on Dec. 17th. His cheeks were red and inflamed-looking; his left arm was red and swollen, with some raised patches, as in Case 1. On the 19th his left forearm was much swollen, measuring two inches more in circumference than the right arm, and was bright red in colour. There were raised papules on his thighs, his eyelids and face were much swollen, and he complained of great irritation. His temperature and pulse rate were normal. This patient did not fully recover till Dec. 31st.

CASE 3.—On Dec. 19th I saw a third patient, a man who had been working with the other two sufferers, but he had only a few papules on the hands.

The head gardener tells me that there have been slight cases since these, after clipping this plant, in spite of the men wearing gloves and keeping their sleeves turned down, and that they quite dread the work. I have examined microscopically leaves of the plant and I find the under surface to be thickly covered with filiform white hairs, having a sharply pointed free extremity with a bulbous expansion where they spring from the leaf. On bruising the leaf in contact with litmus paper an acid reaction is obtained.

The treatment was chiefly local, as there was practically no constitutional disturbance and it consisted in the application of lotions to relieve the irritation which was the worst feature in the cases. It appears to me from the above that there can be no doubt that this plant was the cause of the eruption, especially as the condition had not the appearance of any common skin disease and was most intense on the hands and arms which would mostly come in contact with the plant. No doubt the face and thighs were principally inoculated by the hands, as suggested by Dr. H. R. Crocker in his account of poisoning by *Rhus venenata* and *Toxicodendron*. I imagine that the hairs of this plant, like those of the nettle, secrete an acrid juice and thus cause the inflammation.

Lyme Regis.

NOTE ON A CASE OF PRECOCIOUS CONCEPTION WITH SUBSEQUENT DELIVERY AT FULL TERM.

By JAMES MILNER, M.R.C.S. ENG., L.R.C.P. EDIN.

ON May 11th, at 5.40 A.M., I was called to attend a girl, aged 14 years, six weeks, and four days, who was said to be in labour. Upon my arrival I was told that the child (which was giving audible proof of an independent existence) had been born some 20 minutes. After ligaturing and dividing the cord the placenta was expressed without difficulty. Upon examining the child I found it to present the signs of maturity and to be quite up to the average size. I was unable at the time to weigh and to measure the infant, but I did so when it was three days old, the result being: weight 6¼ pounds; length, 18¼ inches (approximately); fronto-occipital circumference, 13¼ inches; and mento-occipital circumference, 14¼ inches. Probably the weight at birth would be somewhat greater than above stated, for in addition to the usual loss during the first few days there must be taken into account persistent vomiting of the condensed milk given by the nurse in preference to the abundant available maternal supply which early made its appearance.

The subsequent history was uneventful but the progress of the labour was remarkable when the tender age of the mother is considered. The girl said that slight pains which she mistook for stomach ache began about 10 P.M. on the previous day, but no one was disturbed until 4 A.M. on May 11th when the patient's mother thought that labour was setting in. She, however, thought the pains too slight to take much notice of until about 5.30 A.M., when she sent for me and the child was born before the messenger could leave the house.

The patient's height is 56¼ inches and from her general appearance and development she would not be thought to be older than she actually is. Menstruation began at about

---

[1] Brit. Med. Jour., Sept. 30th, 1893, p. 741.

12½ years of age, but the pubes is still devoid of hair, and the only apparent sign of such an event as is here recorded having taken place is the fully-developed milk-laden distension-striated breasts which contrast very oddly with the general appearance of the child-mother.

The cases of full-term labour in mothers of an earlier age than here stated, quoted in works on forensic medicine, are not numerous, for although such premature assertion of their reproductive powers is not uncommon in females of other and warmer climes, such instances are not so common in this country but that they are worthy of being recorded when they do occur, and it would be of interest to know the (verified) age of the youngest mother in this country who has unaided effected the delivery of a full-term living child and without laceration of the perineum, conditions which obtained in this instance.

The case ought to have formed a subject for the criminal court, but upon investigation by the police an offence within the legal time-limit as required by the Criminal Law Amendment Act could not be proved.

WESTMINSTER HOSPITAL.

A CASE OF CIRRHOSIS OF THE LIVER TREATED SURGICALLY BY THE ESTABLISHMENT OF A COLLATERAL CIRCULATION.

(Under the care of Dr. W. MURRELL.)

THE attempt to treat portal congestion by the establishment of a collateral circulation is based on reasonable *a priori* considerations, and as in a certain number of cases the operation has proved successful it now remains only to determine the most suitable cases for the operation and the best method of inducing the formation of collateral vessels. The copious bibliography which Dr. Murrell has appended should prove of value.

A married woman, aged 48 years, was admitted into Westminster Hospital on Oct. 7th, 1901, complaining of enlargement of the abdomen of four months' duration. She had suffered from morning vomiting for six months, the vomited matter often being streaked with blood. There was no definite alcoholic history and there was no peripheral neuritis. In all probability she had had syphilis. She had had 17 children, of whom 11 were living. She had had various miscarriages at two, three, and seven months, and there was the scar of an ulcer over the left tibia for which she had been treated in the hospital in 1897. On admission the abdomen measured 42 inches at the umbilicus and contained much fluid. The liver dulness could not be mapped out with certainty. She was given five grains of iodide of potassium three times a day for a week and then the dose was increased to 15 grains three times a day for a fortnight, but from this she derived no benefit. Two days after admission paracentesis was performed and six pints and 15 ounces of pale, straw-coloured fluid were drawn off. After the tapping the abdomen at the umbilicus measured 36 inches but the fluid speedily reaccumulated and on the 29th the abdomen measured 42½ inches. On that day under gas and ether an incision was made half-way between the umbilicus and the pubes, and a large glass tube having been introduced 14½ pints of serous fluid were syphoned off, much more, however, subsequently escaping. Mr. W. G. Spencer then made another incision two and a half inches in length in the median line above the umbilicus. The abdominal cavity was explored with the finger and the liver was found to be hypertrophic, hard, not very nodular, and covered with lymph. A portion of the omentum was drawn out and stitched with four kangaroo tendons to the abdominal wall. The stitches were removed on the twelfth day and the tube was withdrawn from the lower opening. The patient was able to get up on Nov. 22nd and on the 26th there was very little fluid in the abdomen which measured 36 inches. She was discharged on the 30th, a month and a day after the operation.

On Dec. 24th the patient was readmitted with some return of the ascites. She stated that she had been in fairly good health and had been able to perform her duties. Her temperature was 102° F. and she measured 46½ inches at the umbilicus. She was suffering from bronchitis, for which she was given a mixture of chloride of ammonium, carbonate of ammonium, and iodide of potassium flavoured with liquid extract of liquorice. The back was painted with equal parts of the tinctura and liquor iodi fortis and she had inhalations of pure terebene and pinol. At the expiration of 10 days the bronchitis had disappeared and an attempt was made to promote the development of the superficial blood-vessels in the wall of the abdomen—(1) by chloroform poultices made by sprinkling a couple of drachms of chloroform on several thicknesses of lint; (2) by rubbing in unguentum capsici; and (3) by the local application of oleum cajuputi. The cajuput in addition to acting as a counter-irritant was evidently absorbed and gave much relief to the accompanying flatulence. It was thought advisable to keep the bowels well opened by the administration of a drastic purgative. The compound jalap powder was given in drachm doses every morning but was found to be uncertain and unsatisfactory in its action. Turpeth, the *Ipomœa Turpethum* of the Indian and Colonial Addendum (1900) to the British Pharmacopœia, was then substituted and answered admirably. The official dose of the powder is from five to 20 grains but it was necessary to give the maximum quantity in order to obtain a satisfactory action; this usually produced five or six copious watery motions. On this treatment the patient very greatly improved and on March 18th, 1902, it was found that the superficial veins of the abdomen were much enlarged and the circumference at the umbilicus had fallen to 42 inches. The appetite was good; the urine was abundant in quantity and was free from albumin and sugar. The patient continued to make satisfactory progress, being able to get up for some hours every day until April 1st, when the temperature rose to 102·8°, evidently as the result of some localised peritonitis, and continued high for some days. The inflammation soon subsided and good progress was again made until the 27th, when there was another rise of temperature with a considerable increase in the amount of ascites. The patient was tapped on the 29th and 23 pints of straw-coloured fluid, having a specific gravity of 1015, were drawn off. The patient was relieved temporarily but she gradually became weaker and died on May 7th.

Necropsy.—At the post-mortem examination (which was performed by Mr. E Rock Carling) the body was found to be fairly well nourished. There was a scar of an old surgical wound in the mid-line three inches above the umbilicus. On opening the abdomen there was found recent peritonitis of a fibrinous character matting together the intestines and giving rise to easily separable adhesions of the viscera generally to the abdominal wall. The abdominal cavity contained some pints of turbid fluid, whilst along the course of the descending colon there was viscid, yellowish pus; there was also evidence about the diaphragmatic surfaces of the spleen and liver of old peritonitis with thickening of the capsules and there were a few close and tough adhesions. The liver was firmly attached to the abdominal wall in the epigastric region, the intervening tissue, as was also the falciform ligament, being unusually vascular. Stretching across the abdominal wall from side to side, three and a half inches above the umbilicus, was a band of tissue, apparently organised inflammatory material, vascular, chiefly separable by the fingers, but at the extremities consisting of vessels some of which were as large as a quill and were continued from vessels in the great omentum. The omentum had thus established close connexion with the wall laterally and was slightly adherent in the middle of its extent, but the recent peritonitis made it difficult to say how much of this was of old standing. The liver (weight two pounds and nine ounces) was small, densely fibrotic, and traversed by trabeculæ. There were indications of perihepatitis. The spleen had a thickened capsule and there were indications of recent perisplenitis; it weighed 16 ounces. The kidneys weighed 10 ounces; they were lobulated, the cortex was cloudy, and the capsules were adherent. The heart weighed 10 ounces; the left ventricle was slightly dilated and hypertrophied. The aortic valve held water; the cusps were normal. The mitral valve was somewhat

sclerosed, the chordæ tendineæ were short and thick. The right ventricle and valves of the right side were normal.

—*Remarks by* Dr MURRELL.—The Drummond-Morison operation has been performed so frequently that it can no longer be regarded as a curiosity. The above case is of interest as an illustration of the subsequent treatment adopted. It was a fairly good case for operation but the conditions were not unexceptionable. For example, the patient was subject to bronchitis and for some days after admission her temperature was 102·6° in the evening. The urine had a specific gravity of 1030 and although usually free from albumin it sometimes contained a trace. She had a faint apex systolic murmur heard most plainly at the ensiform cartilage. Her arteries were not rigid and a strong point in her favour was that she was cheerful and good tempered. Her blood was examined on May 3rd and it was found that the red blood corpuscles numbered 5,670 000 and the white 10,200 per cubic millimetre, the hæmoglobin value being 95 per cent. The counter-irritation applied to the abdomen in the manner already described was distinctly useful and the turpeth answered so well that it is somewhat surprising that it is not more commonly prescribed. There is reason to think that the operation materially prolonged the patient's life and had it not been for the frequently recurring attacks of bronchitis the result might have been still more favourable.

S. Talma of Utrecht suggested the establishment of a collateral circulation in the treatment of cirrhosis of the liver in 1887 or 1888 but published nothing on the subject until some years later. Van der Meulen performed the operation in 1888 and the patient died in a few hours from shock. Schelky made an attempt in 1889 and the patient died on the fourteenth day from peritonitis. These cases were not published. Th. Lens[1] of Paramaribo operated on a negro, aged 61 years, on June 6th, 1891, and the patient lived for nearly six months. A necropsy was made and the paper is illustrated by two reproductions from photographs showing the post-mortem appearances of the organs. The article, although reprinted in pamphlet form, attracted but little attention. Dr David Drummond of Newcastle-on-Tyne independently conceived the idea of the operation and it is to him and to his colleague Mr J Rutherford Morison that we are indebted for the suggestion in a form to ensure its general adoption and for placing the procedure on a firm scientific basis. Mr Morison's first operation was on Sept 3rd, 1894,[2] his second was on Oct. 22nd 1895,[3] and the third was on Jan 12th, 1897.[4] Dr H Campbell Thomson in a paper read before the Royal Medical and Chirurgical Society[5] states that the operation was first introduced into this country by Morison and Rutherford, but the only Rutherford of whom I can find any mention in this connexion is Mr Rutherford Morison. Talma[6] has published two papers dealing with the operation, one in 1898 and the other in 1900. He appears not to have been the actual operator but to have delegated the duty to his colleagues, von Eiselsberg and Narath. Alfred Egon Neumann[7] of Berlin on Nov 2nd, 1898, operated on a woman, aged 45 years, with an alcoholic history, who presented an abdomen distended with fluid and a liver which was hypertrophied, hard, and smooth. In the following January she was gaining flesh, the liver was smaller, there was no ascites, and there were well-developed veins about the umbilicus. Neumann considers that we should always bear in mind Talma's requirement that the liver cells be not too greatly impaired in their functional capacities and that every precaution should be taken in selecting proper cases so that discredit may not fall on so valuable an operation. On Nov 4th, 1898, Robert F Weir[8] of New York operated on a man, aged 43 years, a wine-taster, with a much enlarged liver and spleen. The omentum was stitched on each side of the abdominal wound with catgut sutures and in addition the antero-superior surface of the right lobe of the liver, the corresponding diaphragmatic part of the peritoneum, and the parietal peritoneum adjoining the wound were freely scraped with the point of a steel hat-pin. The patient died on the fifth day and at the necropsy extensive peritonitis was found especially in the pelvis. Dr H. D Rolleston and Mr G R Turner[9] have recorded two cases operated on at St. George's Hospital, both in July, 1899. F. Tilden Brown[10] on Sept. 2nd, 1899, operated on a man, aged 43 years, who had been a habitual user of alcohol for many years, chiefly in the form of whisky. A five-inch incision was made between the ensiform cartilage and the umbilicus, and a two-inch incision above the symphysis pubis. Through the lower wound a glass tube one and a quarter inches in diameter was passed into the pelvis behind the bladder. Capillary drainage was provided for by sterile gauze led through the tube. Vomiting was troublesome for the first 48 hours but was controlled by champagne. The patient made a good recovery. In November, 1899, Grinon[11] operated on a woman, aged 47 years, with good results, there being a marked venous development on the abdominal wall, and in the following year Bosowski[12] performed the operation on a girl, nine years of age the subject of cirrhotic liver. On July 25th, 1900, Charles H Frazier[13] essayed the operation under a local anæsthetic, but after opening the peritoneal cavity the manipulation caused so much pain that ether had to be administered. Frederick A. Packard and Robert G Le Conte[14] of Philadelphia operated on two cases, both on Oct. 13th, 1900. Their paper is interesting and to it is appended a list of 22 collected cases. Mr C W Mansell Moullin[15] operated in five cases. Two of the patients died, one from pleurisy four weeks after the operation and the other one week after the operation from exhaustion. The other three patients were discharged relieved, one was lost sight of and the other two were alive and well two years after. Amongst the more recent contributions to the subject may be mentioned a valuable paper by Professor H. Ito and Dr K Omi[16] of Japan in which they record their own personal experiences in five cases and append a bibliography of no less than 75 references. George Emerson Brewer of New York[17] operated on four cases. In the first, that of a woman, aged 58 years, suffering from cirrhosis and ascites, the upper surface of the small nodular liver and the outer surface of the spleen, together with the opposing parietal peritoneal surfaces, were vigorously rubbed with sterile gauze until they bled freely. The peritoneum on each side of the abdominal wound was also rubbed in the same way and the omentum was drawn down and firmly held in contact with the denuded surface by means of sutures which closed the abdominal wound. She died two days later from uræmic coma. The second operation was on a woman, aged 48 years, with cirrhosis and ascites. The mode of procedure was practically the same as in the previous case, but there was a good deal of oozing of blood from the surface of the liver and spleen and the patient died in less than 24 hours. The third case was that of a man, aged 40 years, and he died at the end of five days from peritoneal sepsis. The fourth case was in a man, aged 30 years, with a small, hard, nodular liver and a much enlarged spleen. He died a week after the operation from peritonitis. The last case was in a man, aged 40 years, who had tuberculous consolidation at the left apex with cirrhosis of the liver and ascites. It was apparently a very unfavourable case but he made a good recovery. The author seems to have been unfortunate, there being four deaths out of five cases, but possibly the cases were not selected with sufficient care. To this paper is appended a list of 60 cases in which the operation was performed, but as the information was obtained for the most part from private sources and as references are not given it is difficult for them to arrive at any conclusion as to the value of the operation.

These are all cases of cirrhosis of the liver with a more or less definite history of alcoholism, but in addition Mr J Warrington Haward[18] of St. George's Hospital in August, 1897, operated on a woman, aged 49 years, the subject of calcification of an adherent pericardium with enlargement of the liver from chronic congestion. The relief was temporary and the patient died a year later. Dr. W Ewart showed the specimen at a meeting of the Harveian Society on April 6th, 1899. On Feb. 20th, 1900, Mr

Spencer operated on a patient of mine suffering from Banti's disease. The details of this case have already been published.[19] Pal of Vienna in March, 1902, exhibited at the Gesellschaft der Aerzte two patients operated on by "Talma's method," in which cocaine was employed as an anæsthetic. Both recovered although one had an epileptiform fit with hemiparesis and hæmatemesis. Frank at the same meeting stated that he had performed seven operations recently for cardiac trouble associated with cirrhosis, using in each case Schleich's anæsthesia. He frequently found the omentum greatly shrunken so that a wide area had to be brought into contact with the abdominal wall in order to obtain the necessary anastomosis. In one case he connected the appendices epiploicæ with the large intestine and the patient did well.

It is difficult to say how many cases have been operated on and what is the percentage of recovery. Brewer states that of 59 cases there were 22 deaths and 37 recoveries. M. L. Harris[20] as the result of a study of 48 cases including two of his own, arrives at the conclusion that there was a recovery in 13 per cent. of the "alcoholic cases" and in 15 per cent. of the "mixed cases." Much depends on careful selection and the best results would probably be obtained in the pre-ascitic stage when the diagnosis rests on the alcoholic history with hæmatemesis and enlargement of the liver and spleen.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF PNEUMOCOCCAL ARTHRITIS.

(Under the care of Dr. G. R. MURRAY.)

THE pneumococcus, though generally confining its activities to the lungs, is capable of affecting other parts of the body. An arthritis is probably the most frequent condition produced and may reasonably be looked upon as pyæmic in nature. The severity of the affection of the knee is undoubtedly associated with the antecedent lesion by which the resisting power of the joint has impaired. For the notes of the case we are indebted to Dr N. McCall Smith, late junior house physician

A male, aged 42 years, was admitted into the Royal Infirmary, Newcastle-on Tyne, under the care of Dr. Murray on Jan. 30th, 1901, complaining of pain in the chest and right leg of six days' duration. A fortnight previously he hurt his right knee but was able to work with only slight pain until seized with the present illness. On admission the pulse was 98 and somewhat irregular, the respirations were 44, and the temperature was 103° F He lay flat on his back in bed. His face was flushed and bloated, his eyes were bright and congested, and his expression was anxious. There was a slight restrained cough. The tongue was red and dry and he complained of thirst. The right leg, knee, and thigh were greatly swollen and red. The leg felt "boggy" and pitted deeply on pressure. There was some streaky hyperæmia of the skin of the thigh He also complained of pain in the right shoulder. There was no marked swelling of this joint but there were tenderness on pressure and great pain on movement On examination of the chest the following condition was found. The respirations were hurried and shallow, the left side of the chest being almost motionless. Increased tactile fremitus was present on palpation over the lower lobe of the left lung posteriorly. A friction rub was felt over parts of the same area. Over the left base posteriorly and as high as one inch above the angle of the scapula the percussion note was flat. This extended forwards as far as the anterior axillary line. The other parts of the chest were practically normal. On auscultation the breath-sounds were bronchial in character over the dull area There were some friction sounds and a few clicking râles towards the base. Over the other lung the breath sounds were somewhat coarse and exaggerated.

On Jan. 31st, there was, and had been, no sputum. The exploring needle was inserted into the knee-joint, but no pus was found. A little fluid, mostly blood, was withdrawn. A film prepared from this and stained with carbol-fuchsin showed numerous capsulated diplococci. On the previous night the patient, not having slept for two nights and being in great pain, was given a quarter of a grain of morphia hypodermically and he slept well. On Feb. 1st the respirations were laboured and the pulse was 114, of low tension, and approaching in character to the "water-hammer" pulse. Later in the day the first sound became inaudible On the 2nd, under the influence of repeated hypodermic injections of strychnine, his condition had improved. The consolidation was now limited to a small portion of the upper part of the lower lobe of the lung. The redness and swelling of the leg were extending up the thigh and the pain was very great in the knee. The condition was being treated with opium fomentations. On the 3rd there was blood-stained expectoration for the first time. On examination this was found to be crowded with capsulated diplococci. No consolidation was left except in the upper quarter of the left lower lobe. Redux crepitations were present over most of the lobe There was distinct fluctuation in the right knee-joint. The exploring needle was inserted and thick creamy pus was withdrawn. The pus on examination was found to contain many capsulated diplococci. The joint was opened and the drainage-tube was passed through, no anæsthetic being given. During the following week the patient was in a critical condition. On the 10th the knee-joint was still discharging pus copiously. There were signs of abscess formation on the outer surface of the middle of the right thigh, deep fluctuation being felt. The same could be made out on the outer surface of the middle third of the right leg. On incision into these regions large quantities of creamy pus escaped. On examination the pus in both instances contained swarms of capsulated diplococci. The lung condition had quite cleared up except for some moist sounds. On the 17th there were signs of the right ankle-joint being attacked. The patient was complaining of great pain and the joint was swollen and red. The general condition was still bad. The pulse was 102, irregular, and of low tension. He had muttering delirium at night. The temperature was of a septic type. On the 19th the ankle-joint was incised behind the internal malleolus. Creamy pus escaped and was found to contain numbers of capsulated diplococci. The other incisions were still discharging. The drainage-tube was entirely removed from the knee. On the 26th the patient's condition was practically unchanged. No new focus of suppuration could be found to account for his condition. On March 4th the temperature was still raised and the mental condition was fogged. The lung was quite clear and no new focus of suppuration could be found. On the 8th the right leg had been fomented with boric lint for the last two days. All incisions were doing well, except the one in the middle third of the leg which did not seem to drain properly. On the 15th there were signs of a deep abscess in the muscles of the right calf. There was no definite fluctuation. On the 17th deep fluctuation could be made out in the right calf. On incision about half a pint of pus escaped. A large drainage-tube was inserted. On examination the diplococci were found as before. From the 17th to the 26th the temperature was never above 99°. On the 26th the tube was still in the calf. The patient was quite clear in his mind, the appetite was good, and he was doing very well.

It may be added that subsequently the patient became tired of being in the hospital and insisted on going home. When last seen as an out-patient he was quite well except for some ankylosis of the joints

Remarks by Dr. MCCALL SMITH.—The above case presents many points of interest.

1. As to treatment. Opinions seem to be divided as to the advisability of giving morphia after the initial stages of the disease. I think that in this case it was necessary owing to the fact that the patient had had no sleep for 48 hours on account of the severity of the pain in the knee. If sleeplessness in a case of pneumonia is due simply to the effects of the fever, then I think some other hypnotic such as paraldehyde (from one drachm to two drachms) ought to be used. In other words, morphia should only be used in the later stages when there is a definite pain to be subdued.

2. As to the date of onset of the arthritis This cannot be absolutely fixed but the history of injury a fortnight before his illness gives some colouring to the idea that the arthritis was the primary lesion in this case. The analogy of tuberculous joint disease also favours this view. The condition of the patient's leg on admission shows that there must have been trouble there for some days at least. Against this is the fact that he was able to work till the onset of his illness with only slight pain and the onset was that of a typical pneumonia. Personally, I am inclined to think that the

[19] THE LANCET, June 16th, 1900, p. 1725, and April 26th, 1902, p 1177.

[20] Journal of the American Medical Association, May 3rd, 1902.

patient was suffering from an acute general infection by the pneumococcus.

3. As to the difference of virulence in different lesions. This is striking and shows how little is required to alter the virulence of organisms. In the shoulder there was a simple arthritis, almost like a rheumatic infection, which passed off in a few days. In the knee, which had sustained a slight injury, there was purulent arthritis, the injury having so changed the tissues of the joint that they became a suitable soil for the pneumococci on which they were able to flourish and to reach their maximum virulence and whence they invaded the other tissues of the leg. In the lung we find an ordinary pneumonia which ran a normal course and would not have been dangerous to life *per se*.

4. As to the history of injury. This is definite and the injured part was the first to suppurate. It would be interesting to note in how many of these cases a definite history of injury could be obtained. Among the seven cases published by Dr. N. Raw[1] there is only one in which the previous history gives any clue. In that one there is a history of rheumatism.

5. As to multiplicity of lesions. The number and position of the abscesses are interesting. First the knee was affected; then the thigh was attacked, the organisms being conveyed by the lymphatics. The streaky hyperæmia noted points to this. Then the leg began to show signs of the formation of an abscess; later still the ankle was attacked and last of all another abscess was formed in the leg. I think that the spread of the disease downwards was due to infection spreading along thrombosed veins. The lymphatics are out of the question. Metastasis is unlikely, for if that had been the means, then there ought to have been purulent foci in other parts of the body.

6. As to bacteriology. The feature of interest here is the fact that the only organism that could be demonstrated both in the sputum and the pus was a capsulated diplococcus answering in all particulars to the pneumococcus of Fraenkel. A pure cultivation was obtained from one of the abscesses in the leg and inoculation of a rabbit with the cultures so obtained caused septicæmia. Numerous diplococci were found in the rabbit's blood. The characters of this septicæmia were identical with those of the septicæmia produced by Fraenkel and Weichselbaum by injecting the sputum of pneumonic patients into rabbits.

The case is published by kind permission of Dr. Murray whom I have also to thank for furnishing me with the results of the inoculation of the rabbit.

Medical Societies.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Report of the Committee appointed to Draw up Recommendations as to Compulsory Examination of Hearing-power of School-children.—Exhibition of Cases and Specimens.

A MEETING of this society was held in Dublin on May 31st. By the kind permission of the Rev. the Provost the meeting was held in the Anatomical Department of the Medical School of Trinity College and was also attended by Fellows of the Royal Academy of Medicine and other members of the medical profession. The chair was taken at 11 A.M. by the President, Dr. URBAN PRITCHARD.

A report of the committee appointed on April 14th to draw up recommendations with regard to the compulsory examination of the hearing-power of school-children was presented and unanimously adopted. The following is the text of the report:—

To the Otological Society of the United Kingdom.

GENTLEMEN,—Your committee appointed to consider the desirability of securing for the children of the poorer classes systematic detection and treatment of ear disease and to report at an early date to the society, having carefully considered the reports submitted and the experiences recorded at the special meeting held on April 14th, have arrived at the following conclusions: 1. That there exists amongst the children of the poorer classes a very large amount of ear disease which is preventable and curable. 2. That it is not sufficiently recognised that ear disease in childhood tends to a considerable loss of hearing, health, and life, that it militates against a child's education, and that later on the subjects of it are seriously hampered in their life's work and often incapacitated for the services of the State. 3. That ear disease in children is often not treated, partly owing to neglect, partly to ignorance and to belief in popular fallacies, but more especially to an inability on the part of parents and teachers to detect it. 4. That any scheme having for its object the security of children against the consequences of ear disease to be efficient must provide for thorough and systematic examination and treatment. 5. And, lastly, having regard to the national importance of the subject, we recommend that a memorial embodying this report be submitted to the President of the Committee of the Council on Education.—Signed by URBAN PRITCHARD (President), ARTHUR H. CHEATLE, H. MACNAUGHTON JONES, W. PERMEWAN, and WILLIAM MILLIGAN and W. JOBSON HORNE (honorary secretaries).

Clinical cases were exhibited by Professor STORY, Dr. DEMPSEY, and Mr. R. H. WOODS.

A communication was read from Dr. MACNAUGHTON JONES giving the notes of a case of Double Perforation of the Membrana Tympani by Lightning.

Professor CUNNINGHAM gave a lantern demonstration of the Central Connexions of the Cochlear Nerve in the Orang, Chimpanzee, Gibbon, and Man.

Professor COFFEY demonstrated the Nerve-endings in the Ventral Cochlear Nucleus, the Superior Olive, and the Trapezoid Body.

Dr. DEMPSEY showed microscopic slides of the Membranous Labyrinth.

The PRESIDENT showed lantern slides of Microscopic Sections of the Internal Ear.

Mr. A. H. CHEATLE exhibited specimens of Temporal Bones showing the Petro-squamosal Sinus.

Dr. W. JOBSON HORNE showed preparations demonstrating the Formation of an Abscess Sac at the Site of the Saccus Endolymphaticus.

The visiting members were entertained most hospitably by their Dublin *confrères* and the meeting from the scientific aspect, and in every respect, was an important and successful one.

Reviews and Notices of Books.

Lehrbuch der Nervenkrankheiten für Aerzte und Studirende. (*Text-book of Nerve Diseases for Practitioners and Students.*) By Professor Dr. H. OPPENHEIM. Third Edition. Berlin: S. Karger. 1902. Super roy. 8vo, pp. 1220, 369 Illustrations. Price 27s. net.

THE three years which have elapsed since the publication of the second edition of Dr. Oppenheim's book have seen no striking change in our conception of diseases of the nervous system as a whole; no great discovery has been made to alter our views of the nature of these affections, nor have we learned much as to their treatment; and yet this period has been far from unfruitful. A good deal of useful "spade work" in the shape of the accumulation of observations has considerably widened the details of our knowledge both of the physiology and pathology of the nervous system. Dr. Oppenheim's book has expanded *pari passu* with the increased supply of material. The 985 pages of the second edition have grown to 1220 pages in the volume before us, while the number of illustrations has increased from 287 to 369; it has at the same time been thoroughly revised and brought up to date. The general plan of the book remains unaltered. With a view to supply the needs of the practitioner and student special attention has been paid to symptomatology, diagnosis, prognosis, and treatment, only so much pathological anatomy having been introduced as is necessary to a clear understanding of the clinical features of the various morbid processes.

The book is divided into two parts, the first of which is devoted to the general symptomatology of nerve diseases and to the methods of examination which are commonly employed. Succinct but comprehensive directions are here given for examining muscular movements, reflexes, vaso-motor, trophic, and secretory disturbances, and the other channels through which morbid conditions of the nerves manifest themselves. The actions of the different muscles and groups of muscles are given in some detail with capital photographic illustrations of the attitudes which are assumed in paralysis of them. The investigation of the electrical reactions of muscles and nerves, a subject which the student often finds one of difficulty in practice, is fully described. The second part is subdivided into six sections. In the first of these are discussed diseases of the spinal cord, in the second those of peripheral nerves, in the third those of the brain, and in the remainder neuroses, affections of the sympathetic, and intoxications which particularly influence the nervous system. The consideration of each of these sections is prefaced by a short account of the normal physiology and histology of the parts concerned and the effects of different kinds of lesions are indicated briefly.

---

[1] Brit. Med. Jour., Dec. 21st, 1901.

In his introduction to the diseases of the spinal cord the author alludes to the attack on the "neuron theory" recently made by Apáthy and Bethe. Dr. Oppenheim is of opinion that the commonly accepted view of the neuron as a histological entity may have to be enlarged but that there is no reason to doubt the general truth of the theory. In considering the symptoms produced by injuries of the cord Dr. Oppenheim discusses the cause of the hyperæsthesia of the paralysed limb in Brown-Séquard's paralysis and adds yet another theory to those which have been advanced to account for it. Peripheral sensory stimuli on reaching the cord divide into two components, one of which passes up on the same side to a subcortical centre (not giving rise to sensation), while the other is conducted through the opposite side to a sensory area. A one-sided lesion, barring the passage of the former, diverts it to the path pursued by the latter which, thus reinforced, produces an exaggerated sensation on reaching the cortex. It is an ingenious theory though it does not quite solve the whole problem.

The author's descriptions of the diseases of the nervous system are lucid and graphic. The commoner forms are adequately dealt with while the rarer varieties receive more attention than is usually paid to them in ordinary text-books, a feature of this work which adds greatly to its value for purposes of reference. There is, perhaps, a tendency to make the subject a little too easy. The maladies as described in the book do not display that reluctance to arrange themselves according to types which they are apt to exhibit when met with in real life. However, in a text-book this is to some extent unavoidable and we are bound to say that an unusually large number of anomalous and atypical cases are mentioned in the appendices to the various sections.

With regard to the view which has been advanced that locomotor ataxy is primarily an affection of the posterior roots the author offers no opinion one way or another. In the matter of treatment he has found Frenkel's system of exercises in coördination useful but he warns us not to expect too much from it. While Erb strongly recommended the exhibition of mercurials in tabes Dr. Oppenheim finds them useless in the majority of cases and, rightly as we think, only gives them when they are specially indicated. Galvanism should be tried in every case and its use persevered in for several months. In cases of incontinence of urine he has had striking results from internal faradisation of the sphincter vesicæ. In the treatment of the sequelæ of acute anterior poliomyelitis stress is laid on the value of transplantation of tendons in cases where the joints of the extremities are affected by localised paralyses. This operation might be performed with benefit much more frequently than is generally realised. A page in this section is devoted to the subject of periodical paralyses of the extremities. Some of these are associated with malaria and are relieved by quinine, others are not malarial. The author mentions the case of a boy, aged 13 years, who on recovering from scarlet fever began to suffer from attacks of paralysis which came on at first about once a fortnight. The patient is now grown up and married but still suffers from this curious complaint.

In the next two sections are discussed diseases of the peripheral nerves and those of the brain. In regard to bulbar paralyses, a satisfactory classification does not yet seem to be within sight. Besides the ordinary varieties the author mentions several very interesting forms. In one case he saw bulbar symptoms, the nature of which remained unexplained, in connexion with an attack of laryngismus stridulus. He also refers to three very suggestive instances of bulbar paralysis occurring during typhoid fever. Two of these patients recovered; in the case of the third no histological changes could be found but all parts of the central nervous system were overrun by streptococci. A similar case is reported by Seitz in which pneumococci were found. A fairly full account of myasthenia gravis pseudoparalytica or "myasthenic paralysis," as the author calls it (bulbar paralysis without anatomical lesions) is given. In the earlier cases which are described the bulbar symptoms were the ones which chiefly attracted attention; latterly the proneness to rapid muscular fatigue has been particularly noted. The danger to the patient from this liability to muscular exhaustion was strikingly illustrated in a case under the care of the author. Electrical examination of the thoracic muscles, for instance, at once induced alarming dyspnœa. Mastication and swallowing were performed under difficulties owing to the speedy exhaustion of the muscles of the jaw and the throat. In order to spare the patient this fatigue Dr. Oppenheim caused him to be fed by a tube; unfortunately the spasms set up by the passage of this instrument proved fatal. The author's opinion that infantile convulsions in a certain number of cases are early symptoms of hysteria or epilepsy has, we think, been shown to be correct. He does not, however, give us any guide to the diagnosis of the hysterical or epileptic convulsion in a young child. The majority of children who suffer from eclampsia infantum, we believe, grow up healthy.

The pathology of those attacks which occur in connexion with acute purulent otitis media in young infants and which sometimes resemble a purulent meningitis, sometimes abscess of the brain, but which tend to get well, is obscure. The author believes that they are usually cases of so-called meningitis serosa and recommends lumbar puncture if evacuation of the pus from the ear is not successful.

In the chapter on Neuroses the high standard reached throughout the book is maintained. The author has exercised great judgment in his selection from the vast mass of facts which lies at the disposal of a writer on diseases of the nervous system and has arranged his material very skilfully. While we think that he was wise in refraining from the compilation of a bibliography he would have added to the usefulness of his book by giving references to the authorities quoted in the text. The work is in any case one which every practitioner will find extremely valuable and interesting. We understand that translations of it into Italian, Russian, and Spanish are in preparation.

The Climates and Baths of Great Britain, being the Report of a Committee of the Royal Medical and Chirurgical Society of London. Vol. II. London: Macmillan and Co. 1902. Medium 8vo. Pp. 628–xvi., with seven maps. Price 12s. 6d. net.

WE congratulate the committee of the Royal Medical and Chirurgical Society that undertook this work on the completion of its report. This second and final volume deals with the climates of London and of the central and northern portions of England, together with those of Wales and Ireland. The climates of Scotland are omitted as the necessary local coöperation could not be obtained. The chairman of the committee, Dr. C. T. Williams, has himself contributed the able section on South Wales in which the various meteorological data of the district and their significance in medical climatology are thoroughly discussed. The article on the Midland Counties is by Dr. P. Horton-Smith, by whose energy and industry as honorary secretary to the committee the publication of the present volume has been much accelerated. In fact, he has done for the second volume what Dr. Archibald Garrod did for the first one. In comparison with the large number of seaside places visited by convalescents, overworked persons, and invalids for their tonic climates England is scantily supplied with places suitable as bracing inland resorts—and resorts of this class are much needed for patients who are troubled with biliousness, constipation, and headaches at coast resorts. Dr. Horton-Smith, however, has pointed out various places in the midland counties which can be used for the tonic effects of a visit, and favourable sites for future inland sanatoriums and health resorts have been suggested by other contributors—for instance, by the late Dr. D. J. Leech of Manchester in his article on North Wales. Sir J. W. Moore of Dublin has contributed the longest article in the volume; it would, indeed, constitute a fair-sized book by itself and it deals with the whole of Ireland, excepting Lisdoonvarna, which has been described by Dr Norman Moore. Besides purely medical and climatological considerations a vast amount of interesting information regarding the history, antiquities, and traditions of Irish towns is included, and this at least the medical tourist in Ireland will certainly appreciate. A most important section is that by Dr. W. Ewart on London and "Greater London." In the greatest city of the world the artificial local modifications of climate, resulting from drainage and covering over of the soil, can be admirably studied, and in this respect Dr Ewart's article has a special value of its own. The present volume is, indeed, a storehouse of information and as such should be available as a work of reference by every practitioner in the British Islands. To those in other countries seeking information on British resorts it should prove invaluable and will correct many erroneous notions.

The book is a pioneer one and much ground has been left marked out for future observers to study. It is to be hoped that local practitioners will be stimulated to fill up any gaps and shortcomings which they may detect with the results of their own observations and inquiries, and that such results may afterwards be embodied in a second edition.

Das Wirbeltierblut in Mikrokristallographischer Hinsicht. Von Dr. Med H. U. KOBERT. Mit einem Vorworte von Staatsrat Professor Dr. R. KOBERT, Direktor des Instituts für Pharmakologie und Physiologische Chemie zu Rostock. (*The Microscopical Characters of the Crystals obtained from the Blood of Vertebrates.* By Dr. H. U. KOBERT, honorary physician to the Freemasons' Hospital at Hamburg With 26 Illustrations in the text.) Stuttgart: Von Enke. 1901. Pp. 118.

DR. R. KOBERT remarks in his preface to Dr. H. U. Kobert's work that the micro-chemical characters of the crystals of blood, so important in legal investigations, are not well known to the physicians and apothecaries of Germany who are analysts by profession, and that this ignorance is especially noticeable in regard to hæmochromogen crystals. The present short treatise is designed to enlighten that ignorance. In the animal kingdom there are two kinds of blood which may be termed iron blood and copper blood. Copper blood is represented by hæmocyanin and is found in molluscs, arthropods, and some tunicates, as has been shown by Halliburton. It appears to give colourless crystals. Dr. Kobert's views in regard to the nature of hæmoglobin agree with those of Hoppe Seyler who held that the substance of the red corpuscles was made up of a chemical compound, hæmoglobin, and not of two separate substances, stroma and hæmoglobin. The hæmoglobin in the arteries rich in oxygen he terms arterin; that in the veins poor in oxygen he names phlebin; and various methods are given by which arterin and phlebin crystals can be obtained. Free hæmoglobin only occurs in the blood of living man in hæmoglobinuria or in certain forms of poisoning, but he thinks it to be very questionable whether blood crystals ever form during life, hæmoglobin crystals, supposed to exist in the urinary tubules by various observers, being really crystals of parhæmoglobin. Dr. Kobert passes lightly over the various forms of methæmoglobin, such as sulphmethæmoglobin, cyanmethæmoglobin, peroxide of hydrogen-methæmoglobin, nitrite-methæmoglobin, photo-methæmoglobin, and others. Parhæmoglobin is obtained by treating oxyhæmoglobin crystals with strong alcohol, which without changing their form renders these crystals insoluble in water Parhæmoglobin crystals can be obtained from the blood of animals such as cats poisoned with canadin from the hydrastis canadensis. For the recognition of blood in judicial inquiries hæmatin and hæmin are of great importance A case has been put on record in which the Teichmann crystals of hæmin obtained by the addition of common salt and glacial acetic acid to the stain or spot were recognised to be true hæmin crystals, 40 years having elapsed since the blood was shed. The various methods of obtaining hæmin crystals suggested by Teichmann. Cloetta, Strzyzowski, Wachholz, and Nencki are described very fully Several illustrations are given of hæmochromogen crystals from various animals, as the horse, hamster, guinea-pig, and owl. It seems to be not improbable that hæmochromogen and myohæmatin are identical. Dr. Kobert has collected the various statements that have been published by Nencki, Zaleski, McMunn, and others in regard to hæmatoporphyrin, and points out that if two atoms of oxygen are withdrawn from it phylloporphyrin is obtained which has close relations to the chlorophyl of plants. He considers that the hæmin molecule is composed of two hæmatoporphyrin molecules which are perhaps held together by the iron. A substance intermediate between hæmatoporphyrin and phylloporphyrin is mesoporphyrin, the composition of which is expressed by the formula $C_{16}H_{18}N_2O_2$, the hydrochlorate of which forms beautiful crystals. It is interesting to find that the colouring matter of the blood of animals and of the leaves of plants are nearly allied. There seems to be some difference of opinion amongst chemists in regard to the pigments of various shades that are grouped together under the name of "melanin," some thinking that they are entirely derived from hæmoglobin, whilst others, like R. Kobert, think that a part only has this origin. The last sections of the work are devoted to crystals from white corpuscles and the crystals obtained by Florence from the spermatic fluid which are of importance in medico-legal inquiries, to hæmosterin, blood-serum, fibrin, and formalin pigment crystals. The treatise gives concisely all that is known in regard to crystals obtained from blood and is valuable as a work of reference to all who are engaged in examining such crystals.

Diseases of the Digestive Organs in Infancy and Childhood. By LOUIS STARR, M.D. Third edition, rewritten and enlarged. London Rebman, Limited. 1901. Pp. 448, with illustrations. Price 12s. 6d.

THE volume under review represents a third and revised edition of a work which was originally published by Dr. Louis Starr in the year 1891. Although much old matter which appeared in former editions has been deleted from the pages of the present volume nevertheless the inclusion of many new chapters, notably on Simple Atrophy, Infantile Scurvy, Rickets, and Lithæmia, more than makes good the loss as far as actual size is concerned. One of the special features which marks the revision of Dr. Starr's work is that conformably with the tendency of modern pediatrics the treatment of infantile diseases by drugs and pharmacological preparations is relegated to an entirely subordinate position, while the value of hygienic and dietetic measures in prophylaxis and therapeusis is acknowledged and emphasised in every section of the work. The methods of artificial feeding occupy no inconsiderable portion of the introduction which discusses the general management of children and includes separate chapters on Bathing, Clothing, Sleep, Exercise, and Massage. As regards the general principles of artificial feeding the author insists strongly on the necessity of cleanliness and accuracy in the carrying out of whatever method is employed. The infant is not to be regarded as a mechanical machine constituted on one particular type. Allowances must be made for idiosyncrasies and individual peculiarities. We may, however, point out that an infant is guided in his actions by instincts and emotions and not by intelligence, and hence the suggestion that his own inclination as regards food should be humoured does not strike us as altogether sound. It is generally admitted that one of the first principles of infant feeding is to feed the child and not to allow him to feed himself.

Although the author highly approves of the "percentage feeding" his experience of the results of laboratory milk—that is to say, milk which is prepared according to prescription in the Walker Gordon laboratories—appears to have been most unfortunate According to his view the home modification of milk carried out in accordance with accurate percentage formulæ possesses great advantages over the methods employed in properly constituted laboratories inasmuch as the process entails less manipulative interference with the physical and chemical properties of the natural secretion and consequently with its nutritive value as a food.

In speaking of the rearing of infants on condensed milks, the large quantity of sugar contained in the majority of these preparations is mentioned as possessing unquestionable advantages, inasmuch as an excess of this element tends to "make large babies" and to counteract the tendency to constipation. Most authorities, however, find little to admire in "largeness" of this kind, and although we are aware that Dr. Jacobi among others recommends the exhibition of sugar as a useful laxative it is altogether questionable whether the laxative action is due to anything else than fermentative processes occurring in the bowel. Feeding, however, on condensed milk is not recommended by Dr. Starr as a general practice, since prolonged adherence to this method is likely to lead to the appearance of symptoms of scurvy, a result which is also to be anticipated with any kind of artificial feeding in which the food is not "live." In a series of 25 cases of infantile scurvy which have come under the notice of the author it is interesting to notice that recovery has ensued in the majority of cases by the simple addition of a few teaspoonfuls of orange juice to the ordinary dietary of percentage milk (modified at home). The chapter on Lithæmia—which, by the bye, is not Americanised into "lithemia"—is full of instructive and useful illustration ; although in practice this condition is frequently recognised under various guises it is not usually described as an independent pathological entity in works which treat of the diseases of children. The train of symptoms which are associated with this incomplete metabolism of proteid matter is attributed by the author to defective hepatic function due to hereditary causes or to a diet which is too abundant in nitrogenous elements. "It is quite common," continues Dr. Starr, "for healthy children after a surfeit of food to void urine laden with uric acid, but the patient cannot be classed as lithæmic unless the condition be persistent."

The second part of the volume contains chapters on Affections of the Throat, Mouth, Stomach, and Intestines, Liver, and Peritoneum. Each of them consists of a straightforward account of the etiology, symptoms, and treatment. Although, taken as a whole, the little book presents no striking or original features, it is full of common-sense advice and the rational methods advocated will certainly be appreciated by the patients who are treated on this plan.

LIBRARY TABLE.

Guide to the Microscopical Examination of the Eye. By Professor R. GREEF, Surgeon to the Ophthalmic Department of the Royal Charité Hospital, Berlin. Translated from the Second German edition by HUGH WALKER, M.A. Glasg., M.B. Edin., Assistant Surgeon to the Ophthalmic Department of the Glasgow Royal Infirmary. London: Rebman, Limited. 1901. Pp. 171. Price 5s. net.—This is a practical and most useful little book and should be in the pathologist's room of every ophthalmic hospital. Opportunity, says the Father of Medicine, is fleeting, and many a valuable specimen is lost by the neglect of the surgeon to place the specimen in some preservative fluid immediately after its removal. A very few minutes' delay proves fatal to histological research where the tissue is very delicate, as in the case of the retina. At the same time the author is quite right in stating that the examination of tissues in the fresh state is less practised than it deserves to be. "Many advantages are lost by hardening. A glioma of the retina presents in the hardened and stained preparation a picture quite different from that which it affords in the fresh condition. Every intraocular tumour should be examined in its natural state." With regard to the various methods of fixing and hardening the globe, the directions are very clear and explicit. The book is divided into two parts. The first or general, part gives, besides the methods of fixing and hardening, the imbedding and paraffin processes and the mode of mounting in glycerine. The methods of staining, double and triple staining, and the demonstration of definite substances and tissue elements are fully described. The second or special part is occupied with the modes of demonstrating the structure of the several tissues of the eye, such as those of the cornea, the iris and choroid, the lens, the retina, and the optic nerve We venture to give one example of the plan of the work by quoting the section on that method of triple staining (p. 61) known as Van Gieson's stain. "1. Hardening in Müller's fluid or otherwise. 2. Imbedding in celloidin. Section-cutting. 3 Preliminary staining in Delafield's or Boehmer's hæmatoxylin. It is better to overstain the sections (half an hour) and not, as was originally recommended, to keep them in the hæmatoxylin for only three to five minutes. 4. Thorough washing in water. 5. Staining for a minute or two in a mixture consisting of a saturated aqueous solution of picric acid to which a few drops of a saturated aqueous solution of acid-fuchsin are added before use. The depth of the fuchsin stain may, if necessary, be lessened by immersing the sections in a solution of picric acid. 6. Washing for a minute or two. 7. Alcohol 80 per cent. and 90 per cent. 8. Oil, Canada balsam" In this stain the nuclei are coloured violet, the axis cylinders red, and the medullary sheaths yellow.

Handbook of Public Health. By JOHN ORR, M.D., F.R.C.P.Edin., M.R.C.S. Eng. Edinburgh: E. & S. Livingston. 1901. 8vo, pp. 236. Illustrated. Price 4s. net.—There are already so many volumes which are said to be "hand-books" of public health that we cannot but regret that this author has chosen the word as part of the title of his little book, for it is certainly not a "handbook" in the sense in which many of our large text-books are. It is more elementary in its teaching, suited to the ordinary need of the medical student for general knowledge, not suitable for the requirements of the Public Health diploma student, and therefore would be more aptly termed a "Note-book," or "Outlines," of the art and science of hygiene. It is quite usual to read in a preface that the author considers that "in spite of the already large existing literature of this subject there is a distinct need" for yet another book, wherein old opinions and the views of authorities are too often served up again, embedded in a mass of fresh verbiage with scarcely one new idea throughout." The expression, "need" for another book, occurs in this work and this time we are inclined to agree with the author Text-books on public health which contain full details and which are excellent for examination purposes exist in plenty, but for the ordinary student of medicine who has no time or inclination to devote to the study of a large work on public health and who yet is desirous of becoming familiar with the methods of ventilation, water supply, the disposition of refuse, drainage, and school hygiene there has been, so far as we are aware, no really satisfactory book In this little work students will find just what they really ought not to be ignorant of—rough and ready methods of softening water and of estimating the degree of impurity in respired air and in drinking water There are clear explanations of such ordinary meteorological instruments as the anemometer, the rain gauge, and the barometer We suggest that in the next edition there should be a *short* list of bibliographical references at the end of each chapter At the end of the brief notice of cremation, for example, the reader will doubtless feel that the subject has been quitted too soon and that the author's presentation of it is too sketchy The busy man can seldom attend at the medical library and wishes to waste no time in finding out what book he ought to read. A reference in this case to Sir Henry Thompson's recently published excellent book on cremation would be most useful. The present work has many merits, it is clearly and pleasantly written, is well arranged, and contains a great deal of useful and important information.

New Inventions.

STEREOSCOPE FOR X RAY WORK.

THE illustration shows a new form of Wheatstone's stereoscope for x ray work. The object of it is that negatives may be employed instead of prints, so that both time and trouble are saved, minute changes in structure of bone are much better demonstrated, and the light coming through the negative gives a better solid effect. It can also be used for prints if desired. It consists essentially of a black box with windows cut at each end, one side being covered by a black cloth to admit the head of the observer Into the windows are fitted the various sized frames for the different plates used and these are adjustable if the negatives do not quite correspond. Opal glass screens at each end reflect the light. The stereoscope negatives are placed in the frames at each end and examined in the mirrors in the ordinary way The makers of this instrument are Messrs. Cox and Co

ON THE CURE OF HYDROPHOBIA.

[From Hufeland's Journal der practischen Heilkunde.—March]

Blisters under the tongue in hydrophobia long known in Greece under the name of Lyssais By Dr XANTHOS, *of Siphnus, in Greece.*

At the end of January 1823, as many of my countrymen, compelled by the events which occurred in our country, were travelling from Russia through Germany to Marseilles I saw one of them who came from Trapezunt, who had been bitten by a dog in Hanover.

He had a considerable wound in the middle of the right thigh, which pained him in walking Notwithstanding my advice, that he should stop on his journey till the wound was healed he insisted on setting out the same day with his countrymen and took nothing with him but a little mild salve. Early in the month of May, I met this man again with 27 of my countrymen in Zurich, and was happy to find the wound in a short time completely healed. The man said it was a lucky circumstance that the dog was not mad upon which a Greek, from the Peloponnesus, considerably advanced in years, and well acquainted with the customs of our country observed, that if the dog had been mad it would not have been of much consequence, all that would have been necessary was to cut out the *Lyssais* as soon as possible I immediately put the question to him, 'What do you mean by the *Lyssais?*' He replied, 'In persons who have been bitten by mad dogs, there appear on the ninth day, little blisters under the tongue, which we call *Lyssais;* these must be cut off with a sharp knife, and the bleeding suffered to continue till the poison is discharged.'

Acquainted with the information, which Dr MAROCHETTI had communicated on this subject I considered the testimony of this old Greek extremely important. I inquired of my other countrymen who had lived in various provinces of Greece, whether they were acquainted with this practice, most of them answered in the affirmative, some assured me that they had often witnessed it

As my countrymen were too much dispersed in different places to enable me personally to obtain particular information on this subject from each of them, I sent certain questions from Heidelburg, and obtained from Arau, the following answer from Polychronis, a Thessalian

"If a man is bitten by a mad dog on the ninth day small blisters called *Lyssais* appear under the tongue, they are about the size of a pea, some of them smaller! they are rather dark coloured and look like flesh.—They are situated on the under side of the tongue, near the membranous band, particularly on the side of the veins If you observe the tongue of a sound man and then examine that of a man who has been bitten by a mad dog, you will immediately see the difference.

'As soon as these *Lyssais* are observed, they must be cut out with a sharp knife and the bleeding continued, till the poison is discharged If this is neglected, or deferred too long as for instance till the twentieth day the brain becomes affected, and the patient will die in deplorable convulsions"

ROYAL INSTITUTION OF CORNWALL.—At the meeting of the Royal Institution of Cornwall held at Truro on May 27th an interesting paper by Dr John Beddoe on the history of the human bones recently found at Harlyn Bay, Cornwall was read. Dr Beddoe estimated that the stature of the people whose bones had been discovered was 64 5 inches and 61·2 inches for the male and female respectively Dr Beddoe added that the observations on the discoveries at Harlyn Bay went to swell the mass of evidence that the general population of Britain before the Christian era was not of tall stature.

THE LANCET.

LONDON: SATURDAY, JUNE 7, 1902.

Peace.

ON the evening of Sunday, June 1st, it became known in London that terms of peace had been signed at Pretoria and that the struggle which had weighed so heavily upon England, while it threatened not merely the conquest but the extinction of her adversary, had been brought to a formal conclusion. The news has afforded to all a feeling of sincere relief and thankfulness, for in whatever manner many Englishmen regarded their enemy at an early period of the contest they had learnt to respect him later as a foe full of resource and fighting desperately in a hopeless cause, while the views held with regard to him by those who had returned from the seat of war had done much to temper those held by others who had had no such experience. The Boers had been beaten; as far as their fighting capacity was concerned they had been almost annihilated; none, least of all those who had fought against them, wished to see them exterminated. All now hope that the pacification, the settlement, and the rehabilitation of the late republics as British dependencies will proceed tranquilly, rapidly, and effectively, and that south as well as north of the Orange river the signature of the terms of surrender will be followed by lasting peace and revived prosperity.

The task before the representatives of British rule is not light. To a territory the vastness of which it is difficult for us to appreciate at home, but to which they are fully alive, they have to restore its inhabitants and to restore them in such a manner that they will renew their domicile under equal laws obeyed by all and in circumstances that will enable them to become useful citizens under new constitutional conditions. In the Cape Colony as well as in the Boer States the restoration of constitutional government is still a matter for future deliberation and care. No light part of the work of renewing the civil and social life of the tracts laid desolate by war will consist in the difficulty of so restoring the population to their homes that they may be able to support life. Starvation will for some time be one of the dangers that will beset them, while many of them will be living in localities which during the war have proved hotbeds of disease. The burial of the dead has necessarily been hurried in many instances —and this in places which have been, or may become, dwelling-places for the living, while thousands of animals have died and have not been buried at all. Experience in the concentration camps has shown that the humbler classes of the Boer population are entirely ignorant of the rudiments of sanitation and the treatment of the simplest forms of disease, and that they are by no means ready to be instructed or to follow the example set by those whose habits are more in accordance with modern views upon such subjects. Still, no doubt the concentration camps and those in which prisoners of war have been confined will prove to have been educational centres of no mean value, and the lessons learnt in them will be found to bear fruit to some extent as time goes on.

The lessons of the war, however, that should most carefully be laid to heart in the years of peace that all now hope to enjoy, are those which have been taught to the victors. Already the military organisation of our army has been remodelled and the military instruction administered to its members has been completely changed in accordance with the teaching of bitter experience. The fighting force of Great Britain stands now in possession of actual experience of warfare that will meet with respectful regard among other nations. The authorities responsible for the Army Medical Service have also learnt much in the same stern but unrivalled school. They have learnt, or have had the opportunity of learning, its defects of organisation, they have learnt the limits of its resources, and the nature of the resources with which civilian aid, voluntary or otherwise, can reinforce it. They have also been enabled to form opinions as to the best mode of providing for the obtaining and making full use of such extraneous aid in future time of stress. The Royal Army Medical Corps has learnt to the fullest extent the nature of the wounds inflicted by modern artillery and modern small-arm fire, as well as how to adapt the latest discoveries and resources of modern surgical science to the necessarily limited apparatus and equipment of the field hospital. It has had experience of epidemic disease attacking large bodies of troops, and of all the ills that arise from over-fatigue, over-exposure, and a defective food-supply, upon a scale without parallel since the adoption of modern methods of dealing with these difficulties. The authorities have now the opportunity of reviewing in time of peace its successes and its failures, of insuring the repetition of the former should any future occasion arise, and of guarding against the recurrence of any shortcoming where it is possible for human prudence and ingenuity to guard against it. It is easy beforehand to make resolutions that this shall be done, but history contains instances which show that the lessons learnt in war are not always sufficiently remembered when peace gives the opportunity of studying them with effect. The new warrant is a step in advance; it should secure valuable men for the Royal Army Medical Corps. But many directions yet remain in which the welfare of the corps requires watching. The war so recently ended has proved this; the peace now commencing must not lead to forgetfulness.

There is one thing that we can confidently affirm will now be learnt by all those who during the war have worked to save life and to mitigate suffering, and who during the coming months will be returning to their country, and that is, that we at home are grateful for what they have done. If there have been shortcomings here or there, if some have cavilled at this or at that, the fault has been found in some defect of a system which did not adapt itself to exceptional and trying circumstances. For the *personnel* of the surgical and nursing staffs which have done their duty so nobly in South Africa there have been, and will be, nothing but unstinted praise and high honour. They have toiled without rest or remission through the weary months and years. They have endured hardship and courted danger and some have laid down their lives. Some have won the recognition of their heroism in the medals and decorations that are claimed by conspicuous gallantry, but for the most part their battles have been fought unseen, their courage and their endurance have been shown where few were aware of these qualities, or where all were displaying them in an equal degree. Let us not forget those who will never return to receive the meed of praise and let us accord it ungrudgingly to those who now come back to seek rest among their grateful countrymen.

Metropolitan Hospital Sunday Fund.

JUNE 15TH will be Hospital Sunday We publish to-day our annual supplement in which we urge the claims of the London hospitals upon the generosity of the public, and we add the hope that in the year and month of the coronation of King EDWARD VII. the pressing needs of the maimed and sick poor in the great metropolis of his kingdom may not be forgotten. Their claim to consideration may well inspire the eloquence of the preachers in our places of worship at any time, but during such a period as the present one there is need to be more than usually insistent. Many will, no doubt, during the current month exceed their normal rate of expenditure owing to their natural eagerness to exhibit their loyalty and to witness the many interesting spectacles which an occasion unparalleled in their memory will provide. If, however, the Hospital Sunday Fund suffers from the circumstances in which it is thus collected in 1902 it will be clear that, by some, at all events, loyalty will have been displayed and enjoyment sought at the expense of the hospitals of London and of those for whose benefit those hospitals exist. Let us hope, however, that no such reproach will rest on any, but that rather all will give with a generosity exceeding that of previous years, not so much in order that the Hospital Sunday Fund may not suffer by the coronation as in order that in the year of the crowning of their King it may eclipse all its previous records. Let those who give also remember that if their generosity is exceptional in the present year it will bear an exceptional result, for a wealthy friend of the hospitals of London has promised that should the total of the Fund reach £80,000 he will increase it by 25 per cent. Those who realise that through this generous promise every sovereign they give may be worth 25s. to the Fund will, we hope, find an additional incentive in the determination that the imposed condition shall be fulfilled. It will be remembered that the sum realised on Hospital Sunday last year was £51,893, and in the year before £53,504, while the highest sum contributed hitherto has been £60,361, so that there is some need for unusual liberality at the present time

Another circumstance should not be forgotten which may well stimulate generosity On the last two occasions upon which we have pleaded the cause of the Metropolitan Hospital Sunday Fund we have done so with the knowledge that the country was engaged in a desperate struggle with a determined enemy—a struggle which not only was absorbing valuable lives but which was pre eminently a costly struggle, entailing the expenditure of sums of money that probably no other country in the world could have afforded to pay. Meanwhile, every market in the metropolis was feeling the depression in trade consequent on the prolongation of the strife, and almost every man who was called upon to contribute to the Hospital Sunday Fund might fairly have buttoned up his pockets and replied that he was poorer than in other years and so could not afford to give. This, we are thankful to say, is no longer the case to-day The close of the war in South Africa has long seemed imminent, it is now an established fact. Peace has brought promise of prosperity to many, rest from bitter anxiety to others, with, presently, the return of relatives who have for years past faced death and danger and endured wounds or disease. Let those whose relatives have lain in the hospitals of South Africa and those who have been in those hospitals not forget that the surgeons, military or civil, who attended them, as well as the nurses who ministered to their needs, acquired their skill and learnt their duties in hospitals such as they are now called upon to assist, while a large proportion of them were trained in the very hospitals for the sake of which the Hospital Sunday Fund is organised.

In order that lay readers, many of whom have not had the opportunity of judging for themselves, may be able to get a glimpse at the work which is done in the hospitals, as seen by the eyes of those on whose behalf it is performed, we have framed our annual Hospital Sunday Fund Supplement in an unusual form. Those who peruse it will find the testimony of inmates of hospitals, or of persons who have been inmates or of the parents of children who have been inmates of hospitals, taken from their own lips. They will find recorded the gratitude of those whose injuries range from the crushed pelvis and ruptured bladder of the navvy who, in his own words, was "squeedged" against a stanchion by a bale of wool, to the broken leg of the small boy who fell when playing "over-backs" in the street. They will find patients ranging from the young clerk with tumour of the brain or the cable engineer of the *Grappler*—patients who for any ordinary purposes or in the case of any minor ailment would not have applied to hospitals for aid at all—to the children of the humbler classes of working men and the "bargee" who makes his mark because he cannot write his name If they are not satisfied that these are the *ipsissima verba* of the patient, expressing his or her unprompted gratitude, they will find in our columns letters written direct by patients to their nurses after leaving the hospital or by their relatives—letters which we print without alteration of spelling or construction believing them to be most eloquent as they were written (page 1559) We regret that space did not permit of their inclusion in our Abstract supplied to the places of worship The medical man in the exercise of his profession has to meet ingratitude as well as gratitude, whether he works in return for a fee or as a work of charity He will find in the columns of our Supplement that his efforts in the London hospitals, whether he be one of the senior members of the staff or a house surgeon or house physician, are not altogether in vain, but our Supplement is addressed primarily to the public and not to him, and the gratitude sought for was primarily gratitude to the hospital—gratitude, that is, towards the institution, not towards the individual who carries out his garded as essential to a successful vaccination is not duty in it. This gratitude, we need hardly say, extends itself to those whose generosity aids and supports the hospitals and it is to them that we commend our Supplement in order that once more their generosity may be aroused.

The hospitals are not without their enemies. The anti-vaccinationist does not regard the medical profession with favour; probably he is not a liberal contributor to the Hospital Sunday Fund and he may be capable of attempting to dissuade others from supporting it. We recommend our Supplement to his careful consideration. The anti-vivisectionist is a more active foe; he carries out his campaign without shame or scruple and he openly urges the subscriber to hospital funds not to contribute to institutions which are connected in any way with experiments on live animals. Let us ask those who may be prone to listen to the denunciations and assertions of the anti-vivisectionist to consider the cases that we have laid before them, to examine the statement accompanying each of them as to the clinical aspects of each case and the steps taken to remedy it, and to ask themselves what the position would have been in surgery and medicine had no experiments upon live animals ever been made in the world, either formerly or during recent years.

The advocacy of the claims of the Hospital Sunday Fund does not, however, rest with us. The cause of the institutions which exist for the healing of the sick and maimed poor of all creeds and nationalities in this great metropolis is rightly pleaded on this occasion by the ministers of all sections of religious opinion, of all churches and creeds, in places of worship in which they occupy the pulpit. We only venture to supply them with a few facts, should they care to make use of them, in a cause which in itself is enough to stimulate their eloquence to the highest pitch, and we venture also to remind their hearers that there are others who do not invariably attend places of worship who may be willing to give if they are reminded of the call to do so. The golf-links and the motor-car, the bicycle and the river, have their adherents whose first argument, if they were asked why they did not attend Divine worship, would be that they on their day of rest sought the free air in the pursuit of health. These of all others should remember that the hospitals exist to restore health and strength to those whose enjoyment of these blessings is as great as theirs and to whom health and strength are necessary if they are to hold their own again in the struggle for existence. No better opportunity of affording practical help to such as these could be found than is offered by the Hospital Sunday Fund. It has during its existence done incalculable good to the hospitals of London; it has bestowed the sums entrusted to it with impartiality; it has insured that in the institutions to which it contributes all funds disposed of by those institutions shall be administered in a business-like manner and with proper economy. Thus it has afforded a guarantee to its contributors that money given for the benefit of the London hospitals shall benefit those hospitals to the fullest possible extent, without any possibility of its being diverted into any channel not contemplated by the giver. Truly, we may say that the Londoner, in the enthusiasm of his loyalty, in his joy at the knowledge that when his King is crowned his country will be at peace, can devote his thank-offering, be it great or small, to no worthier object than the increase of the efficiency of the Hospital Sunday Fund.

◆

The Lancet Commission on Glycerinated Calf Vaccine Lymphs.

IN a former Report of THE LANCET Special Commission on Glycinerated Calf Vaccine Lymphs, published April 28th, 1900 (page 1227), attention was drawn to the fact that although the lymphs then on the market differed very greatly as regards their bacterial purity they were, taking them as a whole, eminently satisfactory. These results were important, not only because of the general high average of the bacterial purity of the samples examined, but also from the fact that the lymphs placed at the top of the Table[1] retained their vaccinal activity. From a consideration of the present report (see p. 1621 of this issue) it is evident that the general results are in many ways even more satisfactory than were those obtained in the first series of examinations. It must be pointed out, however, that the anaerobic organisms are much more numerous than they were on the first occasion. This, apparently, is to be explained by the fact that the cultures in glucose formate agar were kept under observation for a much longer period than they were in the first instance; the anaerobic columns in the two sets of experiments can therefore scarcely be compared, and these organisms have for the present been practically ignored, though in future it may be necessary to take them into account. As regards the special statements made and the conclusions arrived at in the first report the Commissioners have now little to retract. In fact, satisfactory as the general results of this second inquiry are "there is," to repeat our exact words of two years ago, "still room for improvement since there is yet much diversity in respect to the degree to which extraneous bacteria are present." The results of the investigation carried on by the Commission appear to indicate still more clearly that the efficacy of the vaccine is not necessarily impaired in those cases in which the glycerination has been carried to such a point that practically all the bacteria have been got rid of. It cannot, however, be insisted too strongly that agents for the sale of vaccine lymphs should be careful not to send out lymph of which they do not know the exact date and must avoid sending it out after the date given by the manufacturer as limiting its due period of action. In the case of one lymph there appears to have been a want of uniformity as regards the activity of different batches, and on one occasion at least such lymph was received after the date given by the manufacturer as that defining the trustworthiness of the lymph. The Commissioners have had placed at their disposal the results of a large number of cases in which various vaccines have been used and they are more firmly convinced even than they were by the results of the earlier investigation that the freer the lymph is from extraneous pyogenic and other organisms the less marked will be those inflammatory concomitants which are so familiar to all vaccinators. Much of the irritation that has often been re-

---

A Lecture

ON

ABIOTROPHY.

Delivered at the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, on Feb. 21st, 1902,

BY SIR W. R. GOWERS, M.D. LOND., F.R.S.,
PHYSICIAN TO THE HOSPITAL; CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—Life presents to us a double aspect and so therefore does death. One is its somatic character, the life of the organism as a whole, to which the words "life" and "death" are chiefly applied. Somatic life depends essentially upon the blood, as the familiar words assert, words uttered and written long centuries ago—"the blood which is the life thereof" It depends on the proper constitution of the blood, deficiency or perversion of which will end life speedily or slowly. It depends on the due reception of oxygen by the blood through the lungs. And it depends also, and most of all, on the due movement of the blood by the heart; if the heart is stilled, life ends almost instantly But besides this general life, the termination of which involves that of every part of the body, many of these parts have their own vitality. Some of them may slowly die, while the life of all the rest goes on without impairment. They may die from many causes, *some early, inevitably, from a grave defect of vital* endurance; some much later, the failure being only slightly *premature; and some at various times, apparently from various* causes. When the failure is early it is often due only to a defect in vitality, a defect which seems to be inherent, the tendency thereto inborn. We do not, indeed, apply the word "death" to this slow decay of the elements; we speak of it as "degeneration," but the process is in many cases, perhaps in most, an essential failure of vitality and I think it is instructive to consider the degenerations in this aspect. But in doing so I am met by the difficulty that we have no word by which to designate this conception—a degeneration or *decay in consequence of a defect of vital endurance.*[1] *I do* not like new words—indeed, I dislike them—but if we have a conception for which no name exists which we need frequently to speak of it is not wise, I think, to shrink from an attempt to give it a name. Here the simplest mode of obtaining what we need is to insert the root of *βιος* after the negative particle in "atrophy" which gives us "abiotrophy" *But it is generally better, if you can,* to appropriate what you need than to make it afresh, and we find the word *βιοτροφος* used in the sense of "vital nutrition."[2] If we prefix the negative particle we have the same word, "abiotrophy" If a more general term is desired the adjective "biotic" has been occasionally used in English[3] in the sense of vital, and from this we may form "abiotic" to designate that which depends on defective vitality. A corresponding substantive would be "abiosis," and this also has some warrant. The word *βιωσις* was employed once or twice in old Greek, meaning "mode of life." It is given us by the physician who is more widely known and esteemed on account of the character and precision of his writings and the devotion of his life than any other medical man who has lived—St. Luke. It is pleasant, I think, to take a word from him.[4] So I give you a choice of words by which to designate this unnamed conception.

In most gatherings of men we may see an illustration of abiotrophy. We may perceive an illustration of the failure *of the life of the hair follicles of the scalp which must be the* essential cause of early baldness. We are so familiar with the condition that we do not always perceive the lessons it may teach us. In many men most of the hair follicles die soon after adult life is reached—die beyond the power of restoration. Some, however, persist; around the circumference is a zone in which vitality is retained; elsewhere the failure is absolute and uniform. It is certainly often hereditary, father and son—indeed, also grandfather and grandson—may become bald between the ages of 20 and 30 years. The decay is *practically limited to* the male sex. In other persons and families failure of vitality in the follicles occurs later and is less extensive. In others, again, a luxuriant growth of hair is retained throughout life. I know that baldness has lately been ascribed to seborrhœa, due to organisms, but such a cause, accidental and acquired, fails entirely to account for the more general features of the condition, and, if true, can be only an exciting cause, effective by reason of the failure in vitality.[5]

Without complete degeneration of the follicles they may fail to produce the normal pigment of the hair and early greyness is hardly less common than early baldness. It is not less instructive. It is a qualitative failure, an enduring defect of one function of the follicles. It shows that without the total failure of life part of the work of life may come to an end. That it must be by a chemical process that the pigment is produced I think none can doubt, and that *hair may be blanched by a change in the follicular secretion* is conclusively shown by the case of one-sided greyness of the beard from meningeal hæmorrhage which I mentioned recently in a lecture on Metallic Poisoning[6] Regarding the association of greyness and baldness, not only may the imperfection to which greyness is due be extreme without any tendency to loss of hair, but it is said that baldness in early manhood is never preceded by greyness, and seldom in later life. The persistent luxuriance of growth of the hair when the formation of pigment has ceased is a *familiar fact. It is* also *worthy of note* that even early greyness is met with in each sex and does not present the tendency to affect males only, which is so conspicuous in premature loss of the hair.

I must not be tempted to delay too long at the surface of the body. But we must not pass at once to the nervous system. Between the surface and the nerve centres we *meet with tissues which present* very *striking and* instructive forms of true abiotrophy—the muscles. In the various forms of idiopathic muscular atrophy, in which there is a primary atrophy of the muscular fibres, we have examples of a true abiosis. To all these primary myopathies it has become customary to apply the term "muscular dystrophy," and the custom is convenient, if not quite accurate. The term thus includes both simple muscular atrophy and its well-known congener, pseudo-hypertrophic paralysis. In these the muscular fibres, after full development, cease to maintain their nutrition. They slowly waste and ultimately a large number, most of them in many parts, ultimately perish. The connective tissues between them overgrow by a process we can discuss better in connexion with the nervous system. Its increase may fail to maintain the normal bulk of the muscles, so that these waste conspicuously, sometimes extremely. In other cases this tissue-weed, *as we may regard it,* presents a more luxuriant development and produces fat-bearing cells which so much increase the bulk of the muscle as to cause the enlargement of "pseudo-hypertrophy"

These great variations in the interstitial process compel us to regard the failure of life in the muscular fibres as the essential element of the disease; it is a defect of vital *endurance, truly congenital* in so far as the tendency is concerned. Two other facts indicate the same conclusion. The defect in the muscular system may not only be, as it were, qualitative, it may be also quantitative. Certain muscles may be absent, however early the sufferer is examined, especially the lower part of the pectoralis major and the latissimus dorsi, the two muscles which depress the raised arm and are, *curiously, the least needed muscles of the body,* since gravitation will accomplish in most circumstances that for which they are needed. We have further proof of its so much due to the action of the vaccinal organism itself as to organisms acting as irritants upon the cutaneous tissues The Commissioners have been informed that the best results were invariably obtained with those lymphs which produced late vesiculation, and they repeat the words that they previously employed "that if a lymph be free from bacteria, especially streptococci and staphylococci and if typical vesicles, slow of development, with little inflammatory areolæ and late in coming to maturity, be obtained the patient is properly vaccinated." In the first report they had not obtained sufficient information to be able to give a definite opinion, but, with the information now placed at their disposal they have no hesitation in speaking most definitely on this point. Our readers will notice the practical nature of the hints given in the summarising paragraph of the report dealing with the causes of "bad" vaccination, from which we have freely quoted.

---

[1] This conception of the degenerations of the nervous system was *admirably stated by Dr. F W Mott in his Croonian Lectures for 1900.* But it formed the subject of an unpublished lecture which I gave in 1897 or 1898 and is epitomised, in its essential features, in some remarks which I made at a discussion on tabes at a meeting of the Pathological Society of London on Dec. 5th, 1899, reported in THE LANCET of Dec. 9th, 1899, p. 1591

[2] *Not indeed in classical Greek; it is quoted by Stephanus from* Gorgias Pisides a Byzantine writer of the seventh century (620 A D)

[3] First in 1860. Dr. W B Carpenter added a second adjectival termination and made it "biotical." It exists in French as *biotique*, from the Latin *bioticus* and the Greek *βιοτικος*, from *βιοτος*, and *αβιωτος* had the sense of "lifeless." Thus, "abiotic" is clearly legitimate.

[4] The word, previously used in the Septuagint, comes to us through the author of the Acts of the Apostles, but may have been used by St. Paul since it occurs in his speech before Agrippa.

[5] In curious contrast to the seborrhœal theory is the conclusion of one German writer that early baldness is the result of the habit of daily washing the head

Annotations.

"Ne quid nimis."

SOME POINTS ABOUT THE NAVAL AND ARMY MEDICAL SERVICES

IT may be well to call attention to a letter from the warden of the London Hospital Medical College on "The Royal Navy Medical Service," which appeared in THE LANCET of May 3rd (page 1281), and to the communication of "Parent" in the correspondence columns of this issue because the two letters seem to us to invite comment at the present time. With regard to the first letter, there appears to us to be a good deal that is pertinent and forcible in what the warden of the London Hospital Medical College has to say about the regulations for the Royal Navy Medical Service recently issued by the Admiralty We agree with the warden in thinking that it would be better for a naval surgeon to hold a house surgeoncy at a hospital after, instead of before, his entry into the service and for him to be allowed to count the time whilst so employed as service towards promotion and pension, but we imagine that there might be some difficulty in getting the financial authorities to continue to pay him during that time as if he were in the actual performance of his naval duties. With regard to the communication signed "Parent," we may say that (again speaking generally) naval medical officers express themselves as satisfied on the whole with the new regulations So far as the navy is concerned when apparently disparaging points are selected and no attention is paid to those in which the Naval Medical Service has an advantage over the Army Medical Service the result is likely—as are all partial and incomplete views—to be misleading Take, for example, the question of allowances. In the army officers have to obtain lodgings, board, and servant, while in the navy an officer has a furnished cabin, a servant, and a capital mess—for the latter of which he pays 2*s* a day only An army officer could not live like this on his allowances. From a merely pecuniary point of view, if a man is careful and desirous of saving money, the navy is the better service. But we may deal a little more directly with some of the points raised by our correspondent, and in doing so we have for facility of reference followed them as numbered in his letter 1. In our opinion the words "if" and "may" in the first paragraph of "Parent's" letter can be safely ignored, for we feel confident that if an officer conducts himself properly after entering the service he is sure of promotion, and it would be a bad thing for the service if he had any vested right to this and could claim promotion when he had not so conducted himself as to deserve it. 2. In the Naval Medical Service promotion is given for "distinguished service or conspicuous professional merit" and such promotions are maintained up to the full number allowed. Officers are on the list of staff surgeons—i.e., officially ranking with major—at the present time who have not more than four or five years' service as surgeons 3. Our correspondent's third point is correct and calls for no comment 4 Although all the officers in charge of small hospitals or marine infirmaries belonging to the navy do not get money as "charge-pay" they get it as "hospital allowance," ranging from £39 to £112 per annum. 5. It is correctly stated that full-pay sick leave is limited to three months, but this applies to *all* naval officers and not to medical officers only 6. If there is no additional grant of daily pay accorded to naval medical officers who may qualify as "specialists" it has to be borne in mind that medical officers in charge of flagships where special knowledge of sanitary matters is required receive from 2*s* 6*d* to 5*s* a day extra.

A CITY WITHOUT MEDICAL MEN

THE Americans still have their Dowie, the prophet who was received with such distinct disfavour in this country Recent copies of a curious sheet called *Leaves of Healing* describe the founding, building, and civic incorporation of Zion, a city of several thousands of inhabitants, ruled over by the Rev John Alexander Dowie as a sort of High Priest No medical men are admitted within the walls of Zion which fair city is under the governance of a recently elected mayor and corporation who in their turn are subordinated to the all pervading Dowie and a body suggestively named the "Theocratic Committee." "The exclamation Wonderful! Wonderful!! is not merely upon our lips but upon the lips of all who see—men of the world," exclaims Mr Dowie's paper. "Railwaymen, business men of all kinds, even newspaper men, are amazed at the Fact that Zion City is already a great Reality The newspapers told them it was only 'a scheme,' or 'a dream' or 'a city on paper'" Medical men are not admitted because they are superfluous in Zion. They might be so wanting in a knowledge of etiquette as to interfere with the roaring practice of Dowie and his myrmidons who have apparently worked wonders of late There is a T A Beatty, for instance, a nice old man to judge by his portrait, who has suffered all his life from sick headaches and latterly from a lump upon his chest. He describes his case, *à la* Walt Whitman, thus —

> "About four years ago I had a little lump on my breast.
> It proved to be a cancer
> I did not say much about it to anybody, until I felt sure that it was a cancer
> Those who had seen cancers said it looked like one"

To come to the point, however, when the growth was larger than half a hen's egg Overseer Piper prayed for its disappearance. This was on August 27th, 1900, and, strange to relate, the growth did what we only wish cancers would do—"it ran out, and in four weeks it was gone." "About a week or two after the cancer was killed," Elder Reed exorcised the bad headaches of the same patient. There's evidence for you on the futility of medical men. And if corroborative testimony be needed consider the case of Mrs. Nellie Crain who was "delivered from boils and an abscess in answer to prayer" "I was terribly afflicted with boils,' she writes and what seemed to be an abscess in my side." But the lady wrote to Zion and "after a hard fought battle with the enemy the victory was finally won and I am completely restored." Even more remarkable is the case of the "young lady seriously ill of appendicitis" who wrote to announce her recovery as lately as April 19th last. "She was suffering from what seemed to be appendicitis," but after the usual invocation by a Zionist she "fell asleep" and quickly recovered. Space forbids us to discuss the cases of those who were healed of "measles and polypus in the nose," "measles in the eyes," and a "head and lungs filled up with dirt and dust." Our readers may thirst to learn more about "Miss Ottilia Wilker's testimony of a short limb lengthened," but we cannot find adequate space to deal with this and similar pathological phenomena. We have, however, quoted sufficient to show that Dowie, though an egregious quack, is no fool. He appeals to the more thoughtful among artisans and mechanics who earn good wages and are anxious to show mental activity by revolting against all ancient knowledge. Dowie has quite got rid of the ancient prejudice in favour of poverty, which perhaps militated against some of the teachings of the older saints. The material money-getting element in Zionism and other new American heresies is a strong pillar of support to the new teachers. Some of them promise boundless wealth to those who will merely set their minds on it and Dowie's followers not being students of sociology appear to be multiplying. They present a curious sight to the student of manners in the twentieth century.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

WE understand that the Lord Mayor has kindly consented to allow a public meeting to be held in the Mansion House on July 14th, at 4 o'clock, with the object of appealing for the funds which are absolutely necessary in order to carry out many urgent requirements in this hospital. The need for alterations was pointed out by the commission of inquiry which, it will be remembered, was held last year at the request of the governors. Isolation wards, a laundry, a new operating theatre, and the utilisation or reconstruction of two houses adjoining the hospital with a view to the provision of further accommodation for nurses and out-patients, are amongst the most needed of those requirements, and are all of paramount importance if the institution is to carry on its work under conditions conforming with modern ideas of hygiene and scientific cleanliness. The hospital owes its inception to a Mansion House meeting which was called by the Lord Mayor of London in November of the year 1859 and has, from small beginnings, gradually attained its present position as one of the chief special hospitals of the world. In addition to a large proportion of patients whose condition requires prompt and active medical or surgical treatment many of the cases received at this institution are essentially chronic in their course and often only open to palliative measures of relief, and this fact renders its work very largely supplementary to that of the general hospitals of the kingdom in which acute and curable complaints must necessarily, and do properly, occupy the most important place. The aggregation and investigation of large numbers of cases of nervous disease have led to important advances in classification and diagnosis which are impossible where the numbers are fewer and the opportunities for study are less prolonged. The results accruing from the facilities thus provided have been freely given to the medical world and have promoted in no small degree the science of neurology. The manner in which paralytic and epileptic patients are sent to Queen-square, not only from all over London and the provinces but from distant parts of the empire, testifies to the appreciation on the part of the medical profession of the benefits conferred on these sufferers, and affords ample grounds for hoping that the support of the profession will not be lacking at the present juncture. Members of the philanthropic public who are anxious that their generosity should serve the double purpose of relieving the peculiarly poignant sufferings incident upon diseases of the nervous system and at the same time of aiding such advance of knowledge as may tend to their prevention as well as remedy, must often turn for counsel in regard to appropriate channels to their medical advisers. An opportunity is thus afforded of promoting the welfare of an institution like the National Hospital for the Paralysed and Epileptic. We venture to hope that such opportunities will not be neglected and that the public will respond generously to an appeal which has as its ultimate object the relief of a class of patients whose needs are not at present adequately provided for.

THE PINE-APPLE AS A DIGESTIVE AID.

THE partaking of a slice of pine apple after a meal is quite in accordance with physiological indications, since, though it may not be generally known, fresh pine-apple juice contains a remarkably active digestive principle similar to pepsin. This principle has been termed "bromelin" and so powerful is its action upon proteids that it will digest as much as 1000 times its weight within a few hours. Its digestive activity varies in accordance with the kind of proteid to which it is subjected. Fibrin disappears entirely after a time. With the coagulated albumin of eggs the digestive process is slow, while with the albumin of meat its action seems first to produce a pulpy gelatinous mass which, however, completely dissolves after a short time. When a slice of fresh pine-apple is placed upon a raw beef-steak the surface of the steak becomes gradually gelatinous owing to the digestive action of the enzyme of the juice. Of course, it is well known that digestive agents exist also in other fruits, but when it is considered that an average-sized pine-apple will yield nearly two pints of juice it will be seen that the digestive action of the whole fruit must be enormous. The activity of this peculiar digestive agent is destroyed in the cooked pine-apple, but unless the pine-apple is preserved by heat there is no reason why the tinned fruit should not retain the digestive power. The active digestive principle may be obtained from the juice by dissolving a large quantity of common salt in it when a precipitate is obtained possessing the remarkable digestive powers just described. Unlike pepsin, the digestive principle of the pine-apple will operate in an acid, neutral, or even alkaline medium, according to the kind of proteid to which it is presented. It may therefore be assumed that the pine-apple enzyme would not only aid the work of digestion in the stomach but would continue that action in the intestinal tract. Pine-apple, it may be added, contains much indigestible matter of the nature of woody fibre, but it is quite possible that the decidedly digestive properties of the juice compensate for this fact.

INSANITY IN TWINS.

INSANITY in twins is a rare and interesting condition and one which serves to throw light on the difficult and obscure problem of the constitutional predisposition to mental disease. Instances of insanity in twins are uncommon in the records of medical literature, the few cases known to have occurred in the United Kingdom having been reported by Clouston, Wigglesworth, Mickle, and Turnbull in the *Journal of Mental Science* during the past 25 years. In the *Archives de Neurologie* for May Dr. P. Keraval, the medical superintendent of the asylum at Armentières, and Dr. G. Raviart, assistant medical officer, have reported a case of insanity occurring in twin brothers who had for many years lived quite apart from one another. One of the patients was a man, aged 39 years when admitted to the asylum in

September, 1888. He was married and was the father of two children. The patient's mother was living and well. He was a man of temperate habits and free from syphilis. On admission to the asylum he was suffering from symptoms of general paralysis of the depressed type with delusions that he was dead and had no bodily organs (*délire des négations*) He refused to take food and the disease progressed rapidly and proved fatal in four months from the time of his admission. The twin brother was admitted to the same asylum in November, 1896. He was a temperate man, free from syphilis, married, and the father of five children. There were symptoms of incipient general paralysis on admission, together with failure of memory, great depression, weeping, and delusions that he was ruined and dead—the same type of delusions as his brother had. He suffered from congestive or apoplectiform seizures and gradually grew worse and died in May, 1899 It was a curious fact that his wife, who predeceased him in January, 1899, was a general paralytic. Dr Keraval and Dr Raviart state that the special interest of these two cases lay first, in their twinship, secondly, in the absence of hereditary antecedents of insanity, thirdly, in their freedom from syphilis and alcoholism, fourthly, in the fact that both were married and developed the same form of insanity in adult life, and, lastly, in the fact that where the general paralysis appeared earlier, as in one of the brothers, it ran a more rapid course and resulted in death more speedily

---

DEFECTS OF VISION DUE TO THE USE OF DRUGS.

PROFESSOR G E. DE SCHWEINITZ of Philadelphia has published in the *New York Medical Record* of May 17th a paper on the Deleterious Results of Certain Common Drugs and Narcotics on the Organs of Sight, as observed in a large number of cases under his care in the ophthalmological department of the Philadelphia Hospital during recent years By far the most important of the forms of functional visual defect (amblyopia) met with was that produced by quinine. It appeared in several forms; varying with the dose and with the idiosyncrasy of the patient. Thus temporary dimness of sight, lasting for some hours, might result from the taking of moderate doses of quinine, especially in the case of women of nervous temperament. If the daily dose was large—e g, from 60 to 80 grains of quinine per diem—a second and more serious form of visual trouble followed. Blindness of sudden onset and almost complete in degree resulted, and this condition lasted for some days Ophthalmoscopic examination showed great pallor of the optic discs and blanching of the retina, due probably to a condition of intense ischæmia Quinine in large doses had a toxic action on the ganglion cells of the retina. Treatment consisted in withdrawal of the drug and the administration of digitalis, amyl nitrite, and strychnine. Quinine blindness was very similar to that caused by the salicylates or by antifebrin and the retinal changes observed were very similar Iodoform occasionally, when absorbed from the dressings of wounds and burns or after administration by the mouth, produced amblyopia Alcoholic amblyopia was produced by ordinary alcohol and in a more intense degree by methyl alcohol. Two drachms of the latter had been known to cause blindness. In about 90 per cent of cases of amblyopia from methyl alcohol vision was found to be permanently damaged Essence of Jamaica ginger, bay rum, and essence of peppermint all produced the same results because methyl alcohol was their main ingredient. Treatment in early cases should be directed to the production of sweating by the administration of pilocarpine and to the hypodermic injection of strychnine About 10 per cent of the patients recovered some degree of sight after treatment. As regards tobacco Professor de Schweinitz states that "certain strong forms of tobacco, particularly if smoked in a pipe or on an empty stomach, were specially liable to give rise to amblyopia." Usually some years elapsed before vision was thus affected, the patient passing through a prodromal period during which an indescribable haze or fog seemed to obscure vision Ophthalmoscopic examination at this stage disclosed pallor of the optic disc and the field of vision showed a central scotoma for red and green. If the patient was addicted to alcoholic intemperance a more rapid and marked degree of blindness followed. Histological investigation showed that the retinal ganglion cells in the macula lutea underwent degeneration and that the same change could be traced in the macular fibres of the optic nerve. The actual agent which caused this has not yet been isolated owing to the many active principles present in tobacco besides nicotine, for the latter was not the sole cause of the symptom. In diagnosis it was necessary to look for the possible presence of disseminated sclerosis and Bright's disease, as both amblyopia and central scotoma, as referred to above, might be due to either of these diseases Among forms of amblyopia due to occupation were those occurring among lead and rubber workers, the poison in the latter class of cases being the carbon disulphide used as a solvent for rubber Amblyopia in lead or rubber workers developed gradually after a few months' exposure to the lead or to the carbon disulphide Workers in hat factories and manufacturers of varnish sometimes developed amblyopia from inhaling the fumes of methyl alcohol used as a solvent for shellac and varnish. Amblyopia was also met with as the result of being exposed to, or inhaling, the fumes of nitro or dinitro-benzene a substance prepared in chemical factories and commonly known as essence of almonds

---

THE SANITARY INSTITUTE

THE Sanitary Institute is doing good work and making satisfactory progress and amongst its members are some of the foremost representatives not only of medicine but of the collateral sciences also During late years the membership has substantially increased and branches it is hoped will soon be instituted in India and in New Zealand and other colonies. The institute has the advantage of having the support of the medical, chemical, and engineering professions, so that the subjects discussed at its meetings are approached from several points of view Essentially its object is to promote the advancement of all that pertains to public health matters. That the Sanitary Institute possesses an influential patronage was obvious from the presence of several distinguished persons on the occasion of the coronation dinner which took place on June 2nd at the Midland Grand Hotel, when the Duke of Northumberland—vice-president of the institute—occupied the chair Amongst those on the right and left of his Grace were Sir Joseph Fayrer, Sir Henry Norbury, Surgeon General W Taylor, Sir Francis S. Powell, and Mr A. Wynter Blyth. The speeches related to many interesting questions of sanitary and social science. In proposing the toast of "The Sanitary Institute" the Duke of Northumberland described how he had paid a morning visit to the Parkes Museum in Margaret-street. He compared it to a well stuffed carpet bag and declared that he was distressed to notice that the interesting collection was set out to so little advantage. That defect was, however, to be remedied, and £8000 had been subscribed towards securing a suitable building His Grace particularly warned the members of the Sanitary Institute not to rely too much upon Parliament. The public, he said, were always imagining that new legislation was going to do what they wanted and in the matter of the housing of the working classes that tendency was especially noticeable. He advised local authorities to use to the full the powers they already possessed before seeking to secure new legislation. He then discussed the question of water-supply and pointed out the danger of thinking that legislation which might undoubtedly be good for one part of the country was necessarily good for another part. He took as an example of this the well-known fact that the temperance question would never be solved until it was recognised that one kind of action was necessary in the country and another in the towns. The very varying requirements in different parts of the country had to be taken into consideration and he urged his hearers not to depend too much upon county councils placing themselves in the position of water companies. Mr. Wynter Blyth, in replying to the toast, congratulated the members on the fact that in a few months they would number 3000. The work of the institute had spread to the colonies and when branches were established in India and New Zealand the institution would become imperial and he would propose to alter the title to the Imperial Sanitary Institute. Special interest was attached to the speeches by the Director-General of the Royal Navy Medical Service and the Director-General of the Army Medical Service, both of whom referred to the enormous difficulty of enforcing sanitary principles during a big campaign such as that through which we had just passed. The education of the soldier and the blue-jacket was the only method which would effectually protect them. The dinner was well attended.

A BOROUGH COUNCIL COME TO JUDGMENT.

THE Poplar Borough Council appears to be a body that not only enjoys strong opinions but also does not scruple overmuch in expressing them on occasion. We hasten to add that the particular opinions to which we refer are in the main sound and just, though in venting them too slight a consideration was shown for the difficulties and for the reputation of medical men whose actions had not been in accord with the views of the borough council. The Poplar Borough Council very laudably provides means for testing the diagnosis of, among other diseases, diphtheria. A practitioner, however, within the jurisdiction of the council notified a particular case as diphtheria without having availed himself of the tests supplied by that body. As it turned out, the patient, who was removed as infectious, was not suffering from diphtheria or from any notifiable disorder. In its perhaps righteous indignation the council, it seems to us, "doth protest too much." To begin with, although everyone will admit the value of bacteriological aid in diagnosing diphtheria yet no one would be wise to maintain that there are not plenty of instances in which the diagnosis can be perfectly justifiably made upon clinical evidence alone. Such may have been the case on the occasion to which we refer. Moreover, feeling thus secure of his diagnosis without further help the practitioner may have thought it of great importance that no time should be lost in removing the patient. He may well have considered that it would be a greater advantage to gain time in isolating the case, supposing it to be infectious, than to establish the innocence of the complaint if it was not. Many circumstances may combine to determine a correct line of conduct in cases like these, and while one set of effects of action appeals most strongly to the borough council another set may assume a more prominent position in the mind of a medical man. It is often hard for the layman to realise the difficulty that there may be in distinguishing between diseases that are essentially different in nature and vastly different in the gravity of their results. To the uninstructed it very likely seems strange that there are many cases in which an "ordinary sore-throat" may be almost indistinguishable from so formidable and familiar a malady as diphtheria. Yet every medical man is aware that to make the distinction decisively and at a first examination may be difficult, if not impossible. Nevertheless, it is, of course, all-important to arrive at such a decision at once when there is involved the question of removing a patient who is in a position to infect a large number of other persons. Such a consideration may conceivably excuse even the neglect of precautions admirably provided by a well-advised and energetic borough council.

ALBUMINOUS EXPECTORATION AFTER PARACENTESIS THORACIS.

IN the *American Journal of the Medical Sciences* for April Dr. David Riesman has recorded a case of a very rare complication of paracentesis thoracis—profuse albuminous expectoration. The first case was published by Pinault in 1853. Subsequently cases have from time to time been recorded by continental, British, and American writers. In Pinault's case the patient was a man, aged 34 years, who had had for three months left pleural effusion. Three litres of fluid were removed and the dyspnœa was at once relieved. In the evening the dyspnœa recurred and about a pint of albuminous fluid was expectorated. In 1873 Terillon in his *Thèse de Paris* reviewed the whole subject and collected 21 cases, of which two were fatal. In the case now described by Dr. Riesman the patient was a woman, aged 48 years, who had suffered from cough and occasional attacks of dyspnœa for six months. For some time there had been slight dysphagia. On examination signs of right pleural effusion were found. The neck was enlarged and the natural depressions were obliterated. Above the inner end of the right clavicle was a hard gland. Paracentesis was performed in the seventh intercostal space and posterior axillary line. Three pints of somewhat turbid yellowish fluid were withdrawn. When a little less than a quart had been removed the patient began to cough. At first the cough was dry but towards the end of the paracentesis a little frothy fluid was brought up. As the face became blue and the cough more intense the paracentesis was stopped. During the following six hours about five ounces of turbid amber-coloured fluid covered with a layer of froth half as thick as the fluid and containing a few streaks of blood were expectorated. The patient then was much more comfortable than before the paracentesis. The expectoration, but not the cough, had diminished. Moist râles were heard over the whole of the right lung. On the following day there was a little cough, the dysphagia had ceased, and the right chest was resonant. A fortnight later paracentesis was again necessary and about a quart of fluid was removed. Severe cough again occurred but it was accompanied by only a little tenacious serum. A large hard gland was found above the left clavicle. Over the sternum there was dulness which extended about two inches beyond the left border. Tumour of the anterior mediastinum, probably sarcoma, which was obstructing the veins returning blood from the right pleura, was diagnosed. 12 days later paracentesis yielded more than three pints of fluid. It was followed by severe spasmodic cough but there was no albuminous expectoration. A fortnight later the patient died. At the necropsy sarcoma of the anterior mediastinum was found. The albuminous fluid expectorated was of specific gravity 1018 and coagulated on boiling into a solid mass. In the recorded cases the albuminous expectoration seldom occurred during the paracentesis but generally after an interval varying from a few minutes to half an hour. In rare instances the interval was two hours; in one case it was 18 hours. The symptoms are as follows. The feeling of relief following the paracentesis is terminated by cough and dyspnœa. The cough quickly becomes severe, expectoration increases, and there is a terrible sense of oppression and orthopnœa. Respiration is laboured, the face is cyanosed, the skin is clammy, and the pulse is weak and rapid. The coarse and fine râles of pulmonary œdema are heard. In mild cases the symptoms gradually diminish, sometimes, however, not for 24 hours. In extreme cases the fluid gushes from the nose and mouth in a constant stream and not infrequently death from asphyxia occurs. The amount expectorated varies; not rarely a pint, or even a quart, of fluid is brought up in two hours. The duration of the attack usually is from one to two hours, but six, 12, 24, and even 48 hours have been recorded. The fluid on standing generally separates into three layers—frothy, opalescent and yellowish, and viscid. In the cases recorded the effusions were usually acute. The amount withdrawn was usually large—from 2000 to 5500 cubic centimetres Œdema of the lung on the affected side, sometimes of both lungs, was the principal condition found on necropsy. The albuminous expectoration is probably due to pulmonary œdema. The compressed lung is suddenly released from pressure. Dr Riesman suggests that there is a great afflux of blood, a sort of "congestion by recoil," and that the vessels which have been altered by prolonged pressure are more permeable and allow exudation into the alveoli which is expectorated. Heart disease and morbid conditions of the opposite lung hindering expansion are predisposing causes In all cases, but particularly when these complications are present, aspiration should be performed slowly. If the effusion is large the amount withdrawn at one time should be moderate.

THE OPERATIONS IN CHINA, 1900-1901

IN the second, and concluding, part of the report to which we alluded recently[1] Dr Jacquemin has little to say in favour of the British medical arrangements in China during the recent operations. "It would be unjust," he says in his exordium, "to judge the sanitary department of the English army by the specimens which we have before our eyes here in China. That nation is almost entirely represented by the Indian army, and, as everyone knows, the whole of the old, obsolete *matériel* is sent to India to be used up." Dr. Jacquemin, having sounded his pitch, goes on to make some more remarkable and equally well-founded observations! The medical *personnel* of the British force was drawn from two sources—the Indian Medical Service and the Royal Army Medical Corps. The officers last mentioned, few in number, were exclusively attached to the European troops, and took, moreover, every precaution to avoid being confounded with their comrades of the Indian army. The British sanitary "formations," continues Dr. Jacquemin, "are sufficiently analogous to old French models," but he feels bound to add that with regard to *entretien* "they leave much to be desired" The instruments had wooden handles and the cases apparently dated from a period anterior to Lister. The stretchers used by the British were identical with those long since abandoned in the French army on account of their weight and lack of solidity. For long distances a species of closed litter was employed which, in the critic's opinion, was none other than the French naval *hamac*, only twice as heavy. From the detailed description, however, we seem to recognise a much older appliance—the common or Indian dooly. It was a member of our own Parliament who once upon a time evolved the "ferocious dooly" which pounced down upon a wounded soldier and carried him off to its den, so perhaps we ought not to smile beyond measure. A little further on Dr. Jacquemin draws a pathetic picture of a Sikh soldier in hospital wrapped up in blankets and lying on a haphazard framework supported by four feet with nothing to protect him from a network of stretched cords save a meagre *paillasse* The description is perfect, but that the critic's pity is quite wasted anyone who has been in India will know. A charpoy in the eyes of a native of Hindostan forms a most luxurious bed. It is only fair to Dr. Jacquemin, however, to admit that his criticism does not invariably damn with faint praise. Speaking of drugs and appliances he says: "The supply of medicaments seems abundant and obviously approaches ours from the point of view of its composition." In addition to our own, the medical arrangements of the German, American, Italian, Japanese, and Russian armies are described at considerable length, and for the most part favourably. Dr. Jacquemin finds himself unable, however, to endorse the view of his subordinate, Dr Machenaud, which we recently mentioned,[2] regarding the good quality of the compressed drugs employed in American military hospitals. The question has been for a long time under consideration in the Central Pharmacy of Paris, and, according to Dr. Jacquemin, compression is incontestably the cause of molecular changes which impair the exact composition of the medicaments. So far the number of drugs susceptible of being used in a compressed form is very small Dr Jacquemin's remarks on the English and Russian medical departments in China are supplemented by Surgeon-Major Visbecq, whose short addendum, in the opinion of his chief, was so full of interest that it deserved publication *in extenso* Surgeon-Major Visbecq limits his remarks to matters of detail, selected apparently at random As he himself observes, some of them are the result of a "coup d'œil rapide," while in his Russian section he says: "It was only given me to see the material of a temporary hospital of the second line" Under the heading "Field s hospital" he, in his turn, describes a dooly which he qualifies as well adapted for a hot, pluvial country, only rather heavy and quite unsuitable for difficult roads. In Afghanistan, Chitral, Burmah, and elsewhere the roads cannot be called easy and yet the doolies manage to surmount them.

EXPERIMENTS ON LIVING ANIMALS.

THE recently issued Parliamentary paper dealing with experiments performed on living animals during the year 1901 should calm the agitation, were it possible, of hysterical foes to scientific progress. To begin with, out of 257 licensees 56 performed no experiments at all. That licences and certificates have been granted and allowed only upon the recommendation of persons of high scientific standing and that the licensees are persons who by their training and education are fitted to undertake and to profit by experimental work would probably give little comfort to the confirmed anti-vivisectionist who sees—

"In every hand a knife,
In every knife a villainous intent"

Yet even the "anti-" fanatic should be appeased by the sober and satisfactory statements of the Inspectors, Mr. G D Thane and Sir Thornley Stoker, which show that in no case has a cutting operation more severe than a superficial venesection been allowed to be performed without anæsthetics. As a matter of fact a very large proportion of the 11,645 experiments reported upon were mere inoculation experiments, associated with no immediate pain at all. When painful consequences ensue a condition attached to the licence requires that the animal shall be killed under anæsthetics as soon as the main result of the experiment has been attained In a very large number of inoculation experiments the results are negative and, as the inspectors state, the animals suffer no inconvenience whatever from the operation. A large proportion of these inoculation experiments are necessitated by the requirements of the authorities responsible for the care of the public health. Inoculations are frequently essential for diagnosis, especially of tuberculosis, anthrax, glanders, rabies, and bubonic plague. Five licensees, it is interesting to read, performed 2636 inoculation experiments for testing antitoxins. Everywhere, the inspectors state, the animals were "suitably lodged and well cared for," and the report throughout makes it obvious to any fair-minded individual that not only is great care taken in the admission of investigators to the privilege of a licence but also that no step is missed to insure the experiment being performed with the greatest possible consideration and humaneness.

[2] THE LANCET, Feb. 22nd, 1902, p. 543

THE DISTRIBUTION OF PLAGUE.

THE report of the medical officer of health on the state of plague in Cape Colony for the week which ended on May 10th states that during the period under notice 2 cases were admitted to hospital, 2 persons were found dead, 3 persons died (including persons found dead), 1 patient was discharged cured, and 6 cases remained under treatment on May 10th. For the week which ended on May 31st 52 cases of bubonic plague and 50 deaths were reported at Hong-Kong.

A GAELIC MEDICAL MANUSCRIPT OF THE SIXTEENTH CENTURY.

MEDICAL readers of Gaelic, and perhaps students of the Celtic language in general, will find something to interest them in the April number of the *Caledonian Medical Journal*. In the Manuscripts Department of the British Museum there is an old Gaelic MS. written upon vellum and catalogued as "Additional 15,582," which came into the possession of the Museum by purchase in the year 1845. Dr. H. Cameron Gillies of London, a well-known Gaelic scholar, has examined this work and made extracts from it, together with annotations, a commentary, and translation which fill about 50 pages of the above-mentioned journal. The bulk of the extracts are printed in letter-press with Gaelic or Celtic characters, but there are also five pages of extremely clear and distinct photographic reproductions of portions of the original. Dr. Gillies states that the manuscript bears the date 1563 and belonged to a remarkable family of Highland physicians who were named Beatons or Macbeths and were famous in the medical tradition of the west and north of Scotland. The language of the manuscript is pure Scottish Gaelic and is similar to the language of Argyllshire and the west of Scotland at the present day. Dr. Gillies discusses the question of Irish linguistic forms and affinities at some length.

THE MIDDLESEX HOSPITAL.

AT a meeting of the court of governors of the above hospital held on May 29th an interesting account was presented by the Weekly Board. The "Précis of Transactions" contained many important items. The existence of a clinical laboratory is now a necessity in every large hospital and consequently the establishment of one at Middlesex Hospital supplies a want that has been severely felt. The court at once sanctioned the arrangements that had been suggested by the medical staff. Amongst other improvements that have been undertaken is the conversion of the old "Laffan" ward into a special operating theatre for gynæcological cases. A new laundry is in course of erection and is approaching completion at Hendon and an extension is being made to the nursing home. It thus will be seen that the authorities of the Middlesex Hospital are energetically maintaining the hospital in the state of efficiency of which they have always been proud and that they do not hesitate to undertake any alterations which are likely to prove of advantage in the treatment and care of the patients. The first volume of "Reports from the Cancer Research Laboratories" is now in the press and will shortly be issued. The staff of the laboratories is now engaged on a second volume of the reports which the director hopes to have ready for the press before the end of the year. The board has at present under its consideration recommendations from the Cancer Investigation Committee as to the provision of additional laboratory accommodation and an increase in the present staff of the laboratories. As is well known, there are exceptional facilities for the study of cancer in all its aspects at this hospital and the present arrangements will not allow full use to be made of the large quantity of material available for investigation. We sincerely echo the wish of the board that this work will not be kept back for want of funds. The work which has already been accomplished has received recognition by the committee appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England, and doubtless the department will benefit by the fund which is now being collected to further a systematic investigation of cancer—a work in which His Majesty the King takes the greatest interest.

RARE AND UNUSUAL FORMS OF LEAD POISONING.

WORKERS in lead and lead ores and those who have to handle or to mix paints containing lead are well known to be liable to suffer from lead poisoning. It is stated that no case is recorded of a child having had symptoms of lead poisoning from playing with "tin" soldiers, though children are in the habit of putting them in their mouths. In the *Progrès Médical* of May 10th Dr. Variot, however, records the case of a child who developed paresis of the lower extremities and other symptoms pointing to lead poisoning. It was found that a toy trumpet with a metal mouthpiece in which there was lead to the extent of 88 per cent. was used by the child and was the source of the poisoning in question. In a recent "Thèse de Paris" Dr. Mabit states that he has observed cases of lead poisoning from bullets which had lodged in the body and had not been extracted. Usually in such cases, says Dr. Mabit, no symptoms of saturnism arise because the bullet becomes encapsuled in a firm and dense coating of fibrous tissue and thus remains "isolated." Occasionally, however, portions or fragments of it undergo solution and absorption into the blood and thus bring about symptoms of lead poisoning. Among the cases recorded by Dr. Mabit is one of a young French soldier who was wounded by a bullet received in the war of 1870 during the siege of Paris. The bullet lodged itself deeply in the nape of the neck and was not extracted. Two years later he began to suffer from anæmia, and later, in 1874, violent abdominal pains and colic followed. These symptoms continued from time to time until 1880, when attacks of gout and of eczema supervened. These troubles were all traceable to lead poisoning from the bullet embedded in the patient's neck. The cases above recorded are of interest as illustrating some of the rarer forms of lead poisoning.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.

THIS association gave a most successful dinner at the Café Royal on May 29th at which some 70 members and guests were present. The President of the association (Dr. Frederick S. Palmer) occupied the chair and was supported by Sir William Selby Church, Bart., President of the Royal College of Physicians of London; Sir George Hare Philipson, President of the University of Durham College of Medicine; Dr. James Little, ex-President of the Royal Academy of Medicine, Ireland; Surgeon-General W. Taylor, C.B., Director-General, Army Medical Service; Mr. A. Wynter Blyth, President of the Incorporated Society of Medical Officers of Health; Sir James Crichton Browne; Dr. W. H. Allchin, President of the Medical Society of London; Dr.

Burton Brown, Master of the Apothecaries' Society; Dr. F. G Penrose, Dr. Ernest White, Dr. G Danford Thomas, Dr. H. D Rolleston, Mr. P. J. Freyer, Mr. Thomas Wakley, jun., and others. The President gave the toasts of "The King," "The Queen, and other Members of the Royal Family," and "The Navy, Army, and Reserve Forces." To the latter Surgeon-General Taylor replied. Sir James Crichton Browne proposed "The University of Durham" in eloquent terms and Sir George Hare Philipson, who received quite an ovation, replied. The toast of "The Durham University Medical Graduates' Association" was given by Dr. William Travers and Dr. T. Outterson Wood, honorary secretary for the south, in reply, congratulated the association upon its rapidly increasing numbers, now reaching nearly 500 members, and also upon the highly satisfactory condition of its finances. Dr. A. H Robinson proposed the toast of "The Guests" and Sir William Church, replied. Dr Allchin proposed the health of "The President" in felicitous terms and congratulated him upon the dignity, eloquence, and urbanity with which he had presided over the evening's proceedings. The musical arrangements, under the management of Mr. Arthur E Godfrey, were admirably carried out and added greatly to the enjoyment of the evening. The next annual meeting will be held at Durham University and the annual dinner will be given in the fine old hall of University College, Durham, in September next.

THE PREVALENCE OF SMALL-POX.

THE following figures show the number of patients admitted to the various small pox hospitals of the Metropolitan Asylums Board for the dates mentioned —On Saturday, May 31st, 30 cases; on Sunday, June 1st, 16 cases, on Monday, June 2nd, 33 cases; on Tuesday, June 3rd, 26 cases, and on Wednesday, June 4th, 30 cases. At a meeting of the Metropolitan Asylums Board held at the offices on the Embankment on May 31st it was stated that during the fortnight which ended on Thursday, May 29th, 580 small-pox patients had been admitted to the Board's institutions, as compared with 478 in the preceding two weeks; 78 had died, as compared with 91; and 577 had been discharged recovered, as compared with 467, the total number remaining under treatment being 1319, as compared with 1394 a fortnight before. For the week ending May 31st 25 cases of small-pox were notified in the county of Essex.

THE DISCUSSION ON LEPROSY AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE discussion on leprosy at the Royal Medical and Chirurgical Society next Tuesday is likely to be of exceptional interest. Dr Hansen of Bergen is expected to be present and will probably take part in the debate. Two important papers were read at the last meeting when time did not allow of any discussion. Mr. T. J. Tonkin, who deals with the Soudan district, upholds the opinion that a poor diet, chiefly of vegetables, is a very important predisponent, whilst Mr J Hutchinson contends that no predisposition is necessary and that the bacillus is introduced into the system by means of badly cured fish. Both admit that the disease is communicable from person to person but both regard diet as of primary importance and place contagion in a second position. Mr Hutchinson believes that the transference is effected solely through the stomach and never by touch or inhalation.

THE late Mr Gassiot has by his will, after many pecuniary and specific bequests, left the residue of his estate to St Thomas's Hospital; the sum in question will probably eventually prove to be a very large one but the hospital will only benefit partially at present. We congratulate the hospital authorities as we understand that money is very much needed in order to keep pace with the demands of the time.

AT a meeting of the Society of Apothecaries of London, held on May 13th, the Court of Assistants passed the following resolution—"That as from 1st July next every candidate for the examination in medicine shall be required to produce a certificate or evidence of having received instruction in the administration of anæsthetics to the satisfaction of his teachers at a recognised medical school and hospital."

THE President and Council of the Ophthalmological Society of the United Kingdom are issuing invitations to a dinner which will take place at the Trocadéro Restaurant, Piccadilly-circus, London, W, on Friday, June 13th, at 7 30 P M. Communications concerning the dinner should be addressed to the headquarters of the Society, 11, Chandos-street, Cavendish square, W.

THE annual banquet of the Association of British Postal Medical Officers "to meet the Most Honourable the Marquis of Londonderry, K.G, His Majesty's Postmaster-General," will take place on Thursday, July 17th, at 7 30 P M., at the Whitehall Rooms, Hôtel Métropole. The honorary secretary is Dr Ritchie Giddings, Mansfield-road, Nottingham.

THE President, Council, and professors of University College, London, are issuing invitations to a conversazione which will be held on Thursday, June 19th, at 8.30 P M. Communications regarding it should be addressed to the Secretary, University College, London.

THE summer session of the General Medical Council came to an end on Tuesday afternoon. The pressure on our space caused by the issue of the Hospital Sunday Fund Supplement has prevented us from completing our report this week.

THE METROPOLITAN WATER-SUPPLY. THE LONDON WATER BILL

ON May 27th the Joint Committee of the two Houses of Parliament resumed its consideration of the London Water Bill. All the members of the Committee were present and Lord BALFOUR of BURLEIGH presided. Clause 18 came under consideration. This clause, it may be remembered, deals with provisions as to arbitration. It provides that under the Act—

> A Court of Arbitration shall be constituted consisting of three Commissioners; and the Right Honourable Sir Edward Fry, Sir Hugh Owen, G C B, and Sir John Wolfe Barry K C.B shall as from the appointed day be the Commissioners.

Sub-section 2 makes provision for filling a vacancy in the Court of Arbitration should one arise from "death or incapacity or otherwise." The power of appointment is vested in the Local Government Board.

The first amendment to Clause 18 was moved by Mr. PEMBER, K.C. on behalf of the metropolitan water companies. It was proposed that certain words should be added to Sub-section 1 and be an instruction to the effect that "the Commissioners shall sit together but the decision of the majority shall be binding"

In support of this amendment Mr. PEMBER called attention to Sub-section 8 of the clause which provides that "the Court of Arbitration may act by two of their number and notwithstanding any vacancy"

Mr FITZGERALD, K.C., on behalf of the Local Government Board, declined to accept the amendment on the ground that such a provision would make it necessary that the three arbitrators should sit in every case. *From this it followed* that the illness of one arbitrator would cause a suspension of the proceedings and the resignation or death of one would necessitate the re-hearing of the case.

The Committee declined to accept the amendment.

Sub-section 5 of the clause was omitted on the motion of Mr. FITZGERALD. This sub-section dealt with inquiries held for the purposes of the Act, and it was stated that the Local Government Board proposed to insert "more suitable provisions" at a later period.

Sub-section 7 was the cause of prolonged argument. It provides that—

> Every award, order, and other instrument made by or proceeding from the Court of Arbitration shall be binding and conclusive to and for all intents and purposes, and shall have the like effect as if it had been made by a judge of the High Court, and shall be acted on, obeyed, executed, and enforced accordingly. No such award, order, or other instrument shall be removeable by any writ or process into any of His Majesty's Courts, and the proceedings or acts of the Court of Arbitration shall not (except as hereinafter expressly provided) be liable to be interfered with or questioned by or in any court, or elsewhere, by way of mandamus, prohibition, injunction, or otherwise:
>
> Provided that the Court of Arbitration may at any stage of the proceedings at an arbitration, and shall, if so directed by the Court of Appeal, state, in the form of a special case for the opinion of the Court of Appeal, any question of law arising in the course of the arbitration

On behalf of the metropolitan water companies it was contended that in this sub-section the words "under the Act" should be introduced, and that without the modification of these limiting words there would be no means of questioning any award of the Court of Arbitration, however wrong such an award might be. Under this sub-section it was proposed that an absolutely arbitratory power should be given to the court.

Mr. CLAUDE BAGGALLAY, K.C., contended that the sub-section under consideration made provision for three things: (1) that every award of the court should be binding; (2) that no such award could be removed into His Majesty's courts; and (3) there was a limited proviso concerning appeal in cases of questions of law. He contended that there should be a right of appeal to the House of Lords.

Mr. FREEMAN, K.C., who represented the London County Council, supported Mr. Baggalay's contention. In this Bill it was proposed to do away with the ordinary rights which every litigant would have in any case, however small, although in this case the property dealt with probably involved the largest pecuniary transaction which had ever been referred to arbitration. Lord Balfour of Burleigh had suggested that an appeal might cost the loss of much time. He (Mr. Freeman), however, thought that as soon as it was decided that the water companies must part with their undertakings it would be to their interest to settle the whole matter up and to hand over their stock. It was no less to the interest of the purchasing authority to take over their duties with as little friction as possible. There would, therefore, he contended, be no unreasonable delay, and it was desirable that the ordinary privileges given to litigants should be preserved. He pointed out that the Court of Arbitration was composed of human beings but would make no further reflection on the court.

On behalf of the Local Government Board Mr. FITZGERALD observed that counsel for the water companies and for the London County Council appeared to have forgotten the position of arbitrators in an ordinary case of arbitration. An arbitrator was absolute judge of the facts and there was no appeal from his decision as to the facts; he was also absolute judge of the law unless he stated a case for the opinion of the court, and he might be ordered by the court to state a case should the court come to the conclusion that a question of law had arisen before them. In the present Bill similar provisions had been made. The arbitrators might state their award in the form of a special case; they might state any points arising for the opinion of the courts and they were compelled so to state a case should the Court of Appeal so direct them. An amendment to the sub-section would also be introduced by the Local Government Board that there might be an appeal to the House of Lords should leave to do so be granted by the Court of Appeal. The jurisdiction of the arbitrators ought not to be unduly curtailed and the amendments proposed by the water companies, supported by the London County Council, might indefinitely delay the settlement.

After a deliberation on the question raised, Lord BALFOUR of BURLEIGH announced that the Committee was very evenly divided in opinion concerning it. The powers which it was proposed should be given to the Court of Arbitration were very wide; no exact precedent had been brought forward in favour of the bestowal of such powers and possibly no precedent for such a course could be found. The Committee, however, was of opinion in regard to the proposed amendments that they would be likely if adopted to lead to undue delay in the settlement of the matter. The Committee declined to insert the words "under the Act" and suggested that the representatives of the Local Government Board, of the water companies, and of the London County Council should confer and should try to come to an agreement as to the amendment of the clause.

Sub section 8 then came under consideration. It provides that—

> The Court of Arbitration may act by two of their number and notwithstanding any vacancy in their number. Subject as aforesaid, the court may regulate their own procedure and the procedure at an inquiry held by a commissioner or officer of the court.

On behalf of the metropolitan water companies Mr. CLAUDE BAGGALLAY proposed that these words should be added at the end of the sub-clause: "No metropolitan water company shall be prejudiced by the decision of any question in any arbitration to which it is not a party."

In the course of his speech Lord BALFOUR of BURLEIGH asked the learned counsel if he were not assuming an entire want of intellect on the part of the arbitrators. Finally, the Committee declined to accept the amendment.

Sub-section 9 was next taken into consideration. In the Bill this sub-section was as follows:—

> In determining the amount of water stock to be issued to any metropolitan water company the Court of Arbitration shall not make any allowance in respect of compulsory sale, and shall not take into account any enhancement or depreciation of the market value of any stock or shares of the company which in the opinion of the court was caused by or resulted from the passing or the anticipation of the passing of this Act, but the court may make such allowance as they think just for covering any expenses which have been or are likely to be incurred in consequence of the passing of this Act, and which ought in the opinion of the court to be borne by the Water Board.

On behalf of the metropolitan water companies Mr. PEMBER proposed the following amendment:—

> That the Court of Arbitration shall award to each company compensation for the transfer of its undertaking as if, with the necessary modifications, the law of compensation for the purposes of the Lands Clauses Acts were applicable to the case.

The Committee sat on May 28th when the question of recoupment to the water companies' shareholders came under discussion.

At the sitting on May 29th the chief matters which came under consideration were connected with the property in, and custody of, the books and documents of the water companies.

THE NEW GOVERNOR OF WEI-HAI-WEI.—The Hon. J. Haldane Stewart Lockhart, C.M.G., Colonial Secretary of the Colony of Hong-Kong and Rector of Hong-Kong College of Medicine for Chinese, was presented, by the Members of the Court, the Senate, and the General Council, and the past and present students of the college resident in the colony, with an extensively signed address bound in a handsome cover faced with silver, in the Legislative Council Chamber at Hong-Kong, on April 18th, 1902, on the occasion of his impending departure from Hong-Kong to take up the Governorship of Wei-Hai-Wei. His Excellency Major-General W. J. Gascoigne, the officer administering the government of the colony of Hong-Kong, presided at the meeting and was supported by Dr. Francis W. Clark (dean of the college) and other well-known local men. The Hong-Kong College of Medicine for Chinese was founded in 1887 by Dr. Patrick Manson, C.M.G., when Mr. Stewart Lockhart accepted the office of treasurer which he held until 1895, when he was elected to succeed his Honour Sir Fielding Clarke, Chief Justice, as rector of the college. Mr. Stewart Lockhart said in the course of his acknowledgment of the address that the Government had at last recognised the value of the work of the college and that in this year's estimates was inserted a sum which would allow of a slight honorarium being given to the prosecutors of the work. The Government had also undertaken to establish a dispensary in the western part of Hong-Kong. He added that graduates of the college would be useful in helping the Government to instruct the natives in sanitary matters, although at present students who had qualified in the college were immediately employed by the Government of the Straits Settlements, to whom Mr. Lockhart had written asking them to join the *Hong-Kong* Government in the establishment and maintenance of a medical college.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 15th, 1902.

INTRODUCTORY NOTE

IN making our annual appeal to the public on behalf of the Metropolitan Hospital Sunday Fund, we propose this year to make known the views of a few of those for whose benefit hospitals are built, organised, and supported The advertisement columns of the lay press teem with laudatory letters proclaiming the virtues of quack pill and potion, the infallibility of ointment and embrocation which their manufacturers sell for profit, why should not there be testimonials for those healing institutions which do their work for love? Why should not the hospitals have a good word said for them, which when they balance their books at the year's end, find that their work is carried on at a loss? Why should not those who support them those by whose benevolence alone they exist, see that the work done is good, that it is done well and lovingly, and that there is a warm response of gratitude in the hearts of those for whose sake their money is outpoured?

In collecting the statements that appear below a uniform course has been pursued. A representative of THE LANCET, after communication with the hospital authorities explaining the object of his visit, has gone to the twelve larger general hospitals in the metropolitan area There he has been taken into the wards by members of the staff of the hospital, and has either been conducted to the bed side of patients suitable for his purpose, or has selected at random for himself patients obviously well enough to talk to him In some instances our representative has visited patients who have been in the hospital recently and have returned to their homes. From the lips of these patients he has taken the story of the accident or illness which brought them to the hospital, of the circumstances of their lives when well, and an expression of opinion as to their treatment in the hospital To these statements he has asked each patient to append his or her signature

Those statements we only print in full where the permission to do so was either given voluntarily and unasked, or where on the suggestion being made it was given with eagerness and unmistakeable willingness. Where there was any doubt or hesitation, any shyness lest employers or neighbours might see it, or that it might in some way prejudice the person named, initials only are used and other traces of identity are suppressed But in all such cases we vouch for the absolute accuracy of every tittle of the story In the case of children initials have been used, as their personal consent might not be thought sufficient where their parents could not be consulted To all of these statements is appended a brief exposition of the clinical aspects of the case in question furnished by the house-surgeon or house physician, or by some other member of the staff of the hospital who has had the case in charge, or who has had access to the notes of the surgeon or physician upon the staff of the hospital who had the case in charge.

We ought perhaps to explain the sense in which we have used above the term 'suitable for his purpose" in speaking of the process of selection employed by our Special Commissioner His object in detailing certain cases for consideration has been to give the readers of our Supplement some insight into those positions where but for *immediate* treatment, accompanied by the *best obtainable conditions* for that treatment, the loss of a life would have followed upon the injury within a few hours as surely as night follows day

The treatment in many cases in the accidents wards must be immediate, and it must be carried on in conditions of freedom from possibility of septic contamination, and with a perfection of nursing and attention that cannot be obtained except in a hospital The rich man taken to his own home after being crushed or wounded in the manner described in some of the cases which follow might die while waiting for suitable surgeons, anæsthetists, and nurses to be brought to his bed side, and their skill might be rendered useless by the want of proper conditions for what we might call respectfully the exaggerated asepticism" necessary to save his life These conditions are to be found in the hospital only, and we will *point again*, as we have pointed before in our annual appeal to the benevolent on Hospital Sunday, to the fact *that it is in our hospitals, and in them only* that our surgeons can acquire that skill which when acquired is at the service of rich and poor alike

Our Special Commissioner has prefixed to the patients' statements a few comments, and has also explained the course which he pursued in eliciting the information

STATEMENT BY THE LANCET SPECIAL COMMISSIONER.

I went to the hospitals in quest of material for the Hospital Sunday Supplement of the LANCET without any prejudice or preconception of what I should be told, except possibly a certain misgiving as to whether the gratitude of the patient as a rule would be commensurate with the physical benefit which I knew it was the object of the hospitals to confer Poverty and suffering combined I expected to find, and the exercise of skill to soothe pain, to remedy injury, and to heal disease The result has allayed my misgivings, and exceeded any expectations that, in more sanguine moments, I ventured to form Patients differed in their modes of expression, some were warmer than others, but warmth of expression is a matter of temperament, and illness and pain are not always conducive to enthusiasm even when convalescence has supervened Some too, had more cause of gratitude than others, for they had been saved from worse fates But I found gratitude in all, gratitude fully appreciating that not only kindness, but unremitting care and skill had been bestowed 'I had everything that I wanted night and day" seems to me the most constant form of expression that I remember to have heard used.

It has, of course not been possible to prevent a little monotony in the form of the statements which follow, particularly as it was desirable to adopt a uniform method, asking first the nature of the patient's occupation if any, then as to the injury, and then saying, "Well, what about the hospital?" or otherwise putting the question in a form as little as possible suggestive of the answer.

Naturally, some patients were better adapted to my purpose than others. I heard of one who had made a wonderful recovery after an accident which might have been expected to cripple her for life, and she was said to be proportionately grateful. She had left the hospital cured some time before, and someone suggested that she could be sent for to see me. She was written to, but she did not come; and only then did the sister who had spoken of her as quite an example among patients let out, with a deprecating smile, that on the last occasion when her grateful patient had paid a friendly visit to the hospital, she had been—well, she had treated herself with a little more alcohol than was perhaps prudent, and there had been a difficulty about her admission to the wards. So this one would not do; no more would a patient in another hospital who certainly ought to have been warm in expressions of gratitude for his treatment had it been fair to ask him for a statement which might have been "used against him at his trial." He was lying comfortably in bed with a fractured leg. In front of him was a policeman in plain clothes, who was playing the handy man and putting coals on the fire, while coals of fire were being liberally heaped on the patient's head by kindly sister and nurse, who viewed him with amused and kindly interest. It may be mentioned that accused persons under apprehension, if ill or injured, are treated in hospitals, a constable being left on duty over them, but the peculiar feature of this man's case lay in the irony of the suggested crime through which he had met his injury. He had broken his leg (so it is alleged against him) escaping from pursuit after breaking into one of the collecting-boxes of the very hospital in which he lay! His views of hospital charity ought to have been edifying. Perhaps they were.

I now give the result of my visits as representative of THE LANCET to the twelve great general hospitals of the metropolis:

Charing Cross Hospital.

J—— S——[1] (Diabetes with Mortification of the Toe) says:

"I have been suffering from diabetes and a bad toe. I "am 68 years old and I was employed as porter at the "—— Stores. Since I have been in the hospital I have "been well treated. I don't wish for better treatment "from both doctors and nurses, and I am a great deal "better. I don't think I could have got well if I hadn't "come in. I was an out-patient at another hospital about "15 months ago for the same thing.

"(Signed) J—— S——."

Statement from the Hospital.—J—— S——, age 68, was admitted suffering from mortification of the big toe. In investigating the case, he was found to be diabetic, a condition which was evidently the cause of his complaint. The utmost effort was made to arrest the progress of his constitutional malady, both by dietetic treatment directed to reduce his consumption of sugar and starch, and by the exhibition of morphia in increasing doses, whilst the local lesion was carefully attended to, with the happy result that the spread of the gangrene has been checked, and the toe is now rapidly approaching complete recovery. Needless to say, if this condition had remained untreated, the gangrene would have extended until it had so undermined his general health that recovery would have been impossible, and he would have died from blood-poisoning and exhaustion.

JAMES READ (A Broken Leg) says:

"I live at 35, Muriel-street, Barnsbury. I do not mind "my address being given. I was brought into the "hospital with a broken leg, after having had a fall when "painting a staircase near Charing Cross. I have been "twice in hospitals with accidents before. I have been in "the Royal Free Hospital and St. Mary's, and now I am "in Charing Cross, and I can say that I have always been "treated with the greatest kindness. I am seventy-three "and have been a painter and paper-hanger all my life, "and I could never have got on without the hospitals. I "cannot sign, my hand is too shaky."

Statement from the Hospital.—J. W. Read, aged 73, a painter by trade, was admitted from the casualty department of the hospital, with a bad fracture of both bones of the right leg. Great care had to be taken to prevent the fracture becoming compound. The case was also complicated by the age of the patient, by his having bronchitis and a considerable amount of arterial and kidney degeneration, the result of lead poisoning acquired in the pursuit of his occupation. He had also broken the same leg in the same place some five years previously. After the swelling (which was considerable) had subsided, the leg was taken from the temporary fixation apparatus in which it had been placed, and the fracture set and put up in a swinging splint. After three weeks the fracture has united, and the man has never had the slightest trouble from his accident beyond his enforced absence from work.

S—— K—— (Cyst in Abdomen) says:

"I am eleven years old. I live at Greenwich. I go to "school there. My father is a stoker, and I have one "brother. I came to the hospital two months ago. I had "a great deal of pain and swelling in my stomach. I was "operated on, and I am getting quite well, I hope. I have "been quite happy and comfortable in the hospital.

"(Signed) S—— K——."

Statement from the Hospital.—Patient, a boy aged 11, admitted on March 3rd, 1902, for pain and swelling of the abdomen of three months' duration starting insidiously and accompanied by loss of appetite, some vomiting, and inability to walk about. There was also considerable loss of flesh. The abdomen was found enormously distended, and this was evidently due to an encysted collection of fluid. An operation was performed on May 7, and the abdomen found to contain a large cyst growing between the layers of the great omentum beneath the stomach. The cyst, which contained eleven and a half pints of fluid, was dissected out with some difficulty and removed, and the patient is now making an uninterrupted recovery.

Guy's Hospital.

MEYER SCHMIDT (Strangulated Hernia) says:

"I can speak conscientiously that death was staring in "my face, and that the operation performed on me in the "hospital saved my life. I have the greatest pleasure in "stating anything that I can to help the hospital. Every"thing in my power I shall do when I get out to influence "everyone I can to support the hospital. I have been "treated in every way whatever as kindly and well as "possible. I know that payment such as I could give "would not get me the treatment I have had. The "very first thing in this country that ought to be supported "is the hospitals. "(Signed) MEYER SCHMIDT."

Statement from the Hospital—MEYER SCHMIDT. The patient was brought to the hospital with a very feeble pulse, very collapsed, with a very large hernia, strangulated. It was got back with a good deal of difficulty in an operation which lasted over an hour. He is now going on well.

J—— F—— (Scalp Wound and Immersion) *says:*

"I can only say for the hospital that I have never been "treated kinder anywhere in my life. Everyone has "taken an interest in me. I am 64. I am a lighterman. "I was knocked off a wharf by a truck, and fell into a "barge on my head. I bounced into the water, and was "picked up and brought here. I was attended to instantly "and am getting better. There is no question that "hospitals ought to be supported. If I had money, it "would be the first thing I should think of."

The above statement was read over to the patient, but he was not able to sign it, being still in considerable suffering.

Statement from the Hospital.—J—— F—— was brought to the hospital wet and cold from having fallen into the dependence on a congenital tendency in its occurrence in several members of the same family and chiefly in the males, the girls, who do not suffer, conveying the morbid tendency to their own sons. Girls, indeed, may suffer, but less frequently in affected families than in the isolated cases which we sometimes meet with. Remember that all hereditary and family diseases sometimes arise *de novo*. I shall have to return to the point again, for it is important.

---

[1] omitted at the desire of the patient.

We saw the special tendency of males to suffer from baldness, we shall see the tendency also in the affections of the nervous system; its manifestation in pseudo-hypertrophic paralysis is striking, even more so, I think, than in simple idiopathic atrophy. You may have heard of the group of cases through which Dr. Meryon first made the disease known in this country. Four boys, all the sons in one family, died from it; the girls were unaffected. But I know that one of these has two sons, and both are affected in an extreme degree. Her daughters are quite well. I could give you other examples which have come under my own observation which are equally marked, but the fact is too well known to need further illustration. I will only remind you, before passing from these muscular maladies, of the unequal way in which the muscles suffer. The distribution of the affection is strikingly different from that of those atrophies which depend upon the nervous system, but its localisation should be remembered, and especially that the muscles of the extremities, the hands and feet, suffer least.

Let us pass to the degenerations of the nervous system. In all those with which we are concerned to-day there is a slow decay of the nerve elements which have a common function—a decay limited to these but extending through their entire extent. Our modern conceptions lead us to regard these functional tracts as nutritional entities and to term them neurons. Each depends for vitality on the cell from which the fibres proceed—a chief process ending in a long fibre and short processes quickly branching in the spongy grey matter. We have long recognised this relation to the cell but the change in our conception has come, as you know, from the perception of discontinuity. The division of the fibres (which is really the separation of their constituent fibrillæ) terminates in ultimate branches which seem to end but end in contiguity to others from which they are stimulated. The groups of neurons which are differentiated in function differ also in their tendency to decay—in their vitality. When this occurs slowly it seems to be the result of a slow failure of the influence of the cell on which their vitality depends and the indications of the decay are first seen in the parts which are furthest from the cell—in the extremities of the fibres. But these neurons differ not only in the duration of life but also in its beginning. Not only do they often die at different times but they differ in the time of their development. Some are structurally complete sooner than others and thus are distinguishable in the beginning of life as well as in its ending.

Before we consider the special forms of the slow failure of these neurons, the forms of neuronic abiotrophy, there is another feature of the process of decay which it is important to discern. Whenever the nerve elements waste there is always an overgrowth of the interstitial neuroglia, the connecting and supporting tissue which lies between them. This overgrowth may be, indeed, on first inspection, the most conspicuous element, and its aspect has led the process to be termed "sclerosis." I say "its aspect," because there is generally no increase of consistence in the part so changed. This is generally diminished; the interstitial tissue, which looks so fibrous and firm under the microscope, is really softer than the nerve elements which have perished. This overgrowth has certain features which it is important to recognise. They have special significance in connexion with conditions which we shall presently consider. The neuroglia is a residue of the embryonal tissue from which the nerve elements also develop. When there is local arrest of development of the latter, as in cases of congenital fissures and cavities in the spinal cord, the embryonal tissue remains in tracts adjacent. The two elements, the neural and interstitial, seem to have a common inverse vitality and it is in consequence of this that the interstitial tissue overgrows when the nerve elements decay. When the overgrowth is thus started it often proceeds with an independent energy, in consequence of which it may overstep the strict limits of the degeneration and pass a little into adjacent tracts. It is especially luxuriant where this tissue is naturally most abundant, about the vessels and at the surface of the spinal cord, e g., beneath the pia mater which may thus be thickened. On account of this the nature of the process was for a long time misunderstood. The significance of the long extent of the degeneration, throughout the whole of a single tract of nerve fibres, did not receive its due weight, at any rate from many workers, as an indication that the degeneration of the nerve elements was the primary process. Attention was fixed upon the conspicuous interstitial tissue, and the characters of this were thought to be evidence that it was the primary change and that it started from the vessels or from the membrane. The word "sclerosis" itself made the mistake easier, because there are some morbid processes in which this element *is* the primary one, as in disseminated sclerosis, and a similar change may result from local inflammation. For these reasons the degeneration of the motor tract in the lateral columns of the cord was, and still is, spoken of as "lateral sclerosis" and degeneration of the fibres in the posterior columns is called "posterior sclerosis." I may add that we have another illustration of the tendency to independent growth of this tissue in the fact that the residual tracts which persist when the development of the cord is arrested may take on a new process of growth at some period, usually in early adult life, so as to give rise to that which seems a definite new formation, the condition termed "gliomatosis."

Not only is the secondary overgrowth thus excessive in degree but it sometimes assumes an energy which entails some vascular disturbance, as active tissue-growth is always apt to do. This may even be such as to constitute a process of an inflammatory character and it may even, in rare cases, be attended by hæmorrhage. There may result from this a rapid or even sudden increase in the symptoms not otherwise to be explained. Let me give you an instance. The optic nerve is a structure in which the amount of interstitial tissue which is formed in primary degeneration is exceptionally large. It is so in the simple atrophy of tabes. In this we sometimes have evidence that the interference with function is especially great at the optic commissure, so as to cause temporal hemianopia—an indication that focal damage is added to the primary atrophy. We can understand this if the secondary change assumes at the commissure an inflammatory degree. This is also indicated by the fact that such temporal hemianopia may develop rapidly. Moreover, I have seen one case of the kind, and another has been recorded, in which, when such hemianopia had developed, it progressed to complete loss in one eye and then the remaining half field was suddenly lost, causing sudden complete blindness, as if the vascular disturbance of the secondary process had led to a hæmorrhage at its chief seat. We shall presently see the importance of these considerations.

Let us pass to the special forms of degeneration of the nervous system which seem to be abiotic. We may distinguish certain groups, to which I referred at the outset. The first consists of those in which the failure of vitality occurs before or soon after adult life is attained, and it may be even earlier, soon after structural development is complete. In most cases of this group the relation to an innate tendency is shown by their frequent occurrence in several members of the same family, in several brothers or sisters, and sometimes by their occurrence in more than one generation. But each form, even those in which a family grouping is most marked, may occur in isolation.

The natural transition from the muscular to the nervous system is by the fibres which end upon the muscles, the spinal motor neurons, whose vital centre is the cell of the anterior grey matter of the spinal cord. Note this: different as they are in aspect, of all structures the muscular fibres are nearest to the nerves. The muscular fibre is excited to instant contraction by the stimulus that reaches the extremity of the nerve fibre, which ends in contiguity to the muscle protoplasm, although the two are not continuous. So also the nerve impulse which stimulates the muscle arises, we now conceive, in the extremities of the branching processes of the cell, as the result of an impulse that reaches the ends of other fibres which are contiguous but not continuous. Remember, also, that the life of the muscle depends upon that of the nerve. Slow atrophy of the muscle follows the slow degeneration of the nerve. Perhaps I should rather say the "gentle atrophy" of the nerve, for a reason you will see in a moment. The atrophy might be thought to be due only to disuse, were it not for the change in electrical excitability which so soon presents itself and which you know quite well—the "reaction of degeneration." But if

Thames. He was also bleeding profusely from a large scalp wound which crossed his head almost from ear to ear, and about a quarter of the area of his scalp was torn up from the skull. His immediate danger was death from hæmorrhage aided by the cold and shock of his ducking in the river. The hæmorrhage was stopped by tying a bandage tightly round his forehead, and he was put to bed with hot blankets, etc., for an hour. As soon as he was warm, his head was shaved and the wound washed thoroughly with antiseptic lotions, the hæmorrhage was arrested locally, and the wound sewn up. Thirty years ago this man would almost certainly have had erysipelas from contamination of his wound by the Thames water and his own hair. Owing to the free use of antiseptic lotions he has not developed erysipelas, and it is not likely that he will do so now.

G—— H—— (Broken Leg) says:

"I am the son of a builder's foreman. I was playing "'over-backs' (leap-frog) when I fell and broke my leg. "I have been quite happy in the hospital. I have every-"thing I want. The nurses, they are very kind to me. I "tried to walk on crutches Tuesday night. I have got "three sisters and three brothers, and we all live in three "rooms. "(Signed) G—— H——."

Statement from the Hospital.—G—— H—— had a fractured thigh bone, and through the intervention of the hospital will have a straight leg, less than a quarter of an inch shorter than the leg which is not broken.

ALFRED ROGERS (Cancer) says:

"I am a labourer, a general labourer in London, and I "had been feeling what I came in for for about two months. "I have been in the hospital a month, and I have been "attended in the best possible way, night and day. If I "go out cured, I shall owe it to the hospital I could not "have had the treatment, or anything like it, at home. I "have got a wife and four little ones at home to keep.

"(Signed) ALFRED ROGERS."

Statement from the Hospital.—A case of cancer of the tongue and anterior pillar of the fauces (the front part of the throat). Patient had half his tongue and the part of the fauces where the cancer was removed. If the cancer had spread further back it would have been impossible to take it out. He is going out in a few days.

King's College Hospital.

MRS. LOUISA PIPER (Cerebral Tumour)—this patient had left the hospital for some time[1]—says:

"54, Cochrane-street, St. John's Wood.—I am a married "woman with a family, and I am perfectly willing to have "my name used and to say all I can. After seven years "suffering from epileptic fits and paralysis, I have been "cured at the King's College Hospital. I could not walk. "I had lost the use of my left leg and also the use of my "left arm. I used to have fits every seven minutes, some "worse than others. I have lain unconscious for three "days and known nothing. I have been in six hospitals. "I was passed on to King's College Hospital from another "hospital. My husband is a tailor. We have four little "children and we certainly could not have afforded all the "treatment I have received if there had been no hospitals "I was treated with every kindness in King's College "Hospital I had everything I wished for and the best "of attention. "(Signed) LOUISA PIPER"

Statement from the Hospital.—LOUISA PIPER was admitted to King's College Hospital complaining of fits She began to have twitchings of the left side of her face in 1894, which increased in severity and frequency in 1895, when she had two fits which affected the left arm and leg as well as the face. In 1898 the fits were frequent. In March, 1900, paralysis of left arm and leg made its appearance In the following January she was unable to read on account of her eyes being affected. On admission, the patient had an imbecile look and was unable to feed herself. A tumour of the brain was diagnosed and an operation performed in which part of the skull was opened and the tumour removed. Three weeks after the operation she had regained power in the affected limbs, and ten weeks after the operation she was able to read fairly well with the right eye, and her left eye was much better. She is now able to look after her family and does her own sewing, etc., without glasses. Since the operation she has had no recurrence of the fits.

WALTER BARBER (Cerebral Tumour)—this patient had left the hospital for some time[1]—says:

"I am fourteen. I had been complaining of my head for "two or three years, and been bad for six months I went "into the hospital two years ago and was in ten weeks, "and I have been perfectly well ever since. I was quite "happy and comfortable in the hospital.

"(Signed) W. J. BARBER."

Walter Barber's Mother says:

"I am the mother of Walter Barber, and I cannot speak "too highly of the hospital and the kindness he received "there, and I wish to express the hope that the Hospital "Sunday Fund may do well and the hospitals prosper.— "(Signed) MRS. BARBER."

Statement from the Hospital.—WALTER BARBER, aged 12, was admitted to King's College Hospital in May, 1900. He had been suffering for some months with headache and vomiting—symptoms which had been increasing for two months before admission He had a cerebellar gait, and there was well-marked double optic neuritis. The right side of his head, behind, was slightly more prominent than the left, and pressure over this region caused some tenderness. The swelling was supposed to have originated from a fall downstairs. A tumour in the brain was diagnosed and an operation performed. The skull was opened over the bulging area and a tumour found in the cerebellum and removed. Although very collapsed after the operation he made a good recovery. The optic neuritis gradually got well. In November he was back at school and joining in all the games with the other boys.

S—— C—— W—— (Appendicitic Abscess) says:

"I had 'appendicitis abscess' in my right side, and I've "been in the hospital for 22 weeks. This is the first day "I have been up I have been very happy in the hospital. "I shall be very glad to see my brother and sisters again. "I have three sisters and one brother I came to this "hospital because one of my sisters had been here I now "make myself useful to the sister and nurses when I can. "I can roll bandages. I rolled sixty last night

"(Signed) S—— C—— W——"

Statement from the Hospital.—S—— W——, age 13 (appendicitic abscess), was admitted to King's College Hospital complaining of pain in his abdomen. Patient was very ill Operation was decided on, as an abscess in the abdomen was suspected. An operation was performed and a large abscess found, the pus was let out, and patient gradually recovered.

The London Hospital.

WILLIAM UNDERWOOD (Crushed, Fractured Pelvis and Ruptured Bladder) says:

"I am a married man with five children. I am a B man "in the docks, the first to go on of the extra labourers. I "was working on board a ship in London Dock. I was "down a ship's hold hooking on two bales of wool, when "the crane worked up unknown to me so quick I could "not get away. The two bales struck me in the stomach, "knocking me up against an iron stanchion. They "squedged me till assistance came. They lowered down "the crane by the men holloaing who were down with me, "and with that I fell on my back. I could not move—I "could not move either of my legs. I was brought to the "hospital, and they have treated me grand. Not the

---

[1] The particular value of recording cases of patients who have left the hospital for some time lies in the assumption that the benefits received are permanent.

"King of the country could have better care than I have had. I am very willing to have my name published. I have been to the hospital twice before as an out-patient with dock accidents.

"(Signed) WILLIAM UNDERWOOD."

Statement from the Hospital.—WILLIAM UNDERWOOD, a dock labourer, aged 48, was admitted to the London Hospital after being crushed between a bale of wool and an iron stanchion while working in the hold of a ship in the London Dock. He was extremely bad on admission and was found to be suffering from a fractured pelvis and a ruptured bladder. He was operated on a few hours after admission and is now progressing very satisfactorily, his life undoubtedly having been saved by the operation.

ALEXANDER HUNTER (Concussion, Scalp-wounds, Bruises) says:

"I am a boatswain in the merchant service. I arrived in London at Euston Station a fortnight ago, and, proceeding on my way to the Sailors' Home in Wells Street at midnight, I was set on by four men. I was knocked *unconscious and robbed of everything I had. I tried to* get on down to the Sailors' Home. The last thing I remember was sitting on a doorstep, and I next remember arriving at the hospital. Directly I arrived my head was dressed and I was sent up to bed. I don't remember much about it. The next day I had three fits and was very near dead. I honestly believe I should have been dead if I had not been taken to the hospital. Since then I have had every attention paid to me. Everyone has seemed to do everything they could for me. As for the sisters and nurses, they could not be more thoughful, or clever, or kind. "(Signed) A. W. HUNTER."

Statement from the Hospital. — ALEXANDER HUNTER, a sailor, aged 32, was admitted into the London Hospital unconscious. He had been knocked down while walking along the street, kicked and generally maltreated, and then robbed. When he came into the hospital he was unconscious, and had several lacerated wounds on the scalp, and many bruises about the body. He remained unconscious for some hours, but regained consciousness, and after his wounds had healed was able to be discharged fit for work.

This is a good example of a very important type of case, many of which would die, and many also would, after recovery, be subject to fits and other cerebral disturbances, but for the existence of hospitals where they can be taken in and watched, so that operation can be resorted to as soon as necessary.

J—— C—— (Tuberculous Disease of Thigh and Knee joint) says:

"I have been in the hospital now for 8 weeks. I have been in it many times before. I get better each time, and my leg gets bad again. I came in this time to have it taken off, but the surgeon said it was much too good a leg to be taken off. My father works for the Borough Council of Stepney, as a scavenger. I have been treated very well at the hospital, both in and out. I am sure I I don't know what I should do without it.

"(Signed) J—— C——."

Statement from the Hospital.—J—— C——, aged 19, has been suffering from tuberculous disease of the femur and knee-joint since she was twelve years old. She has been in the hospital five times before, and has had six operations for removal of diseased bone. At the last operation the whole of the part of the bone that was diseased was removed, and she is now on a fair way to recovery with a very useful leg.

H—— C—— (Varicose Veins) says:

"I am a temporary porter in the Post Office, and I had the offer of the appointment permanently, provided that I was medically fit. I failed in this through having varicose veins. I have been operated on in the hospital, and my operation has proved successful, so that if I get appointed I shall owe it to there being a hospital to go to, as I could not have had it done in my own home

"(Signed) H—— C——."

Statement from the Hospital.—H—— C——, a porter, aged 23, was admitted into the hospital with varicose veins of the leg. These were removed by operation, and he is now quite fit to return to his old employment.

Middlesex Hospital.

HENRY DOLLY (Stab in the Abdomen) says:

"I am a coach painter by trade. I was walking along the street in which I live, when I unintentionally came up against a foreigner, an Italian bootmaker, who lived in the same house. There was no quarrel between us before, but he raised a stick, and when he was prevented from striking he drew a knife on me, and stabbed me in the abdomen. I did not know I was wounded when I fell, and became unconscious, coming to just as I was being taken into the hospital. A very short time after I got the wound I was under chloroform. I cannot tell about what was done to me, no one was allowed to speak to me for a fortnight, not even the police; I was in the hospital and convalescent home about two months altogether, and I know that the hospital saved my life. The judge at the sessions, when he sentenced the man who stabbed me, told him that but for the hospital he would have been standing charged with murder, so that the hospital saved two lives! He got fifteen months. As for my treatment at the hospital and at the convalescent home they treated me splendid. I could not wish for better. I also must thank the hospital for its care of my little daughter. She has just returned home for the third time quite well, thanks to the hospital. She suffers from fits. "(Signed) H. DOLLY,

"120, Cleveland-street."

Statement from the Hospital.—HENRY DOLLY was brought to the hospital after receiving a stab in the abdomen. A wound was found in the abdominal wall about an inch and a half long, situated to the left of the middle line about an inch below the umbilicus; a piece of omentum about two inches long was protruding from the wound. An operation was performed immediately. The abdomen was opened, and the protruding piece of omentum ligatured. A wound was found in the stomach, about three quarters of an inch long. This was closed by two rows of sutures. The abdominal cavity was sponged out, and the wound in the abdominal wall closed in layers. The patient has since been at the convalescent home at Clacton, and has now returned to his home and his work.

REBECCA PEACOCK (both Legs cut off in the "Tube") says:

"I was standing on the platform at a station of the 'twopenny tube' with my little boy. I think I fainted; anyhow, I fell down on the line, falling into the hole between the lines. I remember my little boy, who fell in too, catching hold of me and saying 'Mother.' I came to, but I remember very little about it. I was brought to the hospital and everything done for me that could be done. I am now getting better. As for my treatment in the hospital I could not ask for any better. Everybody is kindness itself; most considerate they are; as gentle as anything. I must have died if they had not brought me in here. My husband is a postman, and I have three children I need hardly say that had there been no hospital I don't know what would have happened.

"(Signed) REBECCA PEACOCK."

Statement from the Hospital.—REBECCA PEACOCK was brought into the hospital with both legs cut off below the knee and attached by tendons only. She was in a state of collapse and in great pain, which was immediately relieved by the injection of morphia. She was then placed under anæsthetics. The ragged pieces were removed, and the ends of the stumps trimmed up. She is now going on well.

Royal Free Hospital.

E—— K—— (*Cancer of the Breast*) *says:*

"When I am at work I am a counter-assistant in a refreshment bar, at 14s. a week, and was at work right up to the day I came here. I came to the hospital in

"March, having noticed that there was something wrong
"with me. I was told that it was cancer, and was
"operated on three or four days afterwards, so that I have
"been in seven weeks, and shall be glad to be up and out.
"I certainly could not have afforded surgeons and nurses,
"if there had been no hospital to go to, and I suppose
"I should have had to have gone on getting worse with
"cancer. Of my treatment in the hospital I willingly say
"that everyone has been very kind, and I have been very
"comfortable. (Signed) E—— K——."

Statement from the Hospital.—E—— K—— manageress of a tea shop, aged 37, was admitted to the Royal Free Hospital suffering from cancer of the left breast. She had noticed her trouble for six months, but had not taken advice about it. A very extensive operation had to be done, as glands in the armpit were also affected. This operation required two surgeons, an anæsthetist, and a nurse, and could not possibly be done in a patient's home except at great expense.

MRS. CLAMPITT (Cancer of the Tongue) says:

"I am a widow, and have been for many years, but I
"have always been able to keep myself, though very poor.
"I do needlework and work in gentlemen's houses. I used
"to do a good deal of that kind of work. When my mouth
"got bad I had to come into the hospital, and I had part
"of my tongue cut out. That was two years ago. Since
"then I have been able to work, and when I couldn't I
"had to go into the workhouse. Now I am in again and
"have had another operation. I haven't seen myself, but
"I have been very much cut about. It's a wonderful
"operation from what I hear the doctors say, and when
"you are old these operations tell upon you. I am, as you
"see, getting on. As for the hospital, everything is good.
"Nothing is too good to say about it. Everybody is kind
"here to you, and as for the sister, she is an excellent
"angel. Of course they have their rules, and you have to
"abide by them, but if you are not comfortable it's your
"own fault, so I say. They are going to send me to a
"home on Monday. I am only too happy for my name to
"appear. "(Signed) MARY CLAMPITT."

Statement from the Hospital—MARY CLAMPITT, aged 54, was admitted to the Royal Free Hospital in Jan., 1900, suffering from cancer of the tongue. This was removed, and the patient was able to go out in a few weeks talking very well. In April, 1902, she was again taken in, as recurrence had taken place in the glands in the neck. A very extensive operation had to be done, including the removal of the common carotid and internal jugular vessels. Notwithstanding this, she was able to go out quite well on May 12. But for the powers of antiseptic surgery, such an operation could only be fatal.

PRIVATE J. TWITCHETT (Cancer of the Jaw) says:

"I am a private in the Essex Regiment, and this is the
"second time I have been in this hospital. I was operated
"on on the 19th of March, and am nearly well now I
"was able to go back to the army before after being in
"the hospital, and if my jaw gets well enough for me to
"be able to shave I shall be able to go back to the army
"again, entirely thanks to the hospital. I was sent to
"the London Free Hospital from Warley. As to my
"treatment in the hospital, you have everything you wish
"for night and day. "(Signed) PT. J. TWITCHETT."

Statement from the Hospital.—JAMES TWITCHETT, soldier, was admitted to the Royal Free Hospital suffering from an extensive growth of cancer on the left lower jaw. The whole of the growth was removed, including the half of the lower jaw. The operation was extensive and difficult, but the patient was up and in the square at the end of a week. His disfigurement, now that his beard has grown, is comparatively trifling.

St. Bartholomew's Hospital.

WILLIAM TAYLOR (Ruptured Spleen) says:

"I am William Taylor, and am eight years old. I goes
"to school at All Saints' School, Muriel-street. My father
"cuts glass. I was running across the road to get to the
"other pavement and I was knocked down by a cart and
"the cart went over me, over my stomach. It hurt me
"very much. A man, he was a soldier, picked me up and
"a policeman brought me to the hospital on the cart that
"ran over me. It was a four wheel van with one horse, a
"lady was driving it and a boy was in it. I lay on a bed
"in the surgery, I remember, when I got to the hospital,
"and then I had an operation. After the operation they
"brought me to this ward. I know what the name of the
"ward is—Pitcairn I now feel I am better. I am going
"to Swanley on next Friday to the convalescent home for
"nineteen days. Then I shall go home. I have five
"brothers and two sisters. I shall be glad to be with
"them again. They come and see me on Sunday from two
"to three. I am very glad I was brought to the hospital.
"We have only three rooms at home so I could not have
"been so comfortable. I have been very comfortable and
"happy in the hospital. I like the nurses.
"(Signed) WILLIAM TAYLOR."

William Taylor's Father says:

"I am the father of William Taylor. I saw my son
"at the hospital the evening he was brought in, and I
"went to see him after the operation I was allowed to
"come and see him as often as I liked; he was on the
"dangerous list—on the slate—for a fortnight, and I think
"they have done a wonderful cure for him. He has
"everything he wants, so he says, whenever he wants it
"and seems thoroughly happy, in fact he seems as if
"he'd like to stay. You can use the name and address as
"much as you like.—R. TAYLOR, 31, Rodney-street, N."

Statement from the Hospital—WILLIAM TAYLOR, aged 8, was run over on March 27 by a van. He was brought to the hospital in a very collapsed condition, and had obviously received some severe internal injury. He was taken to the theatre and given chloroform. The abdomen was opened and found to be full of blood. A large rent was found in the spleen, and this was carefully sewn up, so as to stop all the bleeding. The boy made an uninterrupted recovery, and is now waiting for a vacancy in our convalescent home at Swanley. Had not the operation been done so expeditiously, he would undoubtedly have died in an hour or so.

R—— T—— (Perforated Gastric Ulcer) says:

"I am nineteen next August. I was a general servant;
"I was taken bad while I was out in service. I was
"washing up the dinner things, when I was suddenly
"taken with the pain, and sat down and screamed. I had
"felt as if I had indigestion for nine months My mistress
"gave me some cold brandy and water, and told me to go
"and lie down I tried to go to bed but couldn't, I was
"in such pain. My mistress undressed me. I lay in bed all
"that night and next day. It was the next evening that my
"mother came and fetched a doctor. He gave me a medicine,
"and ordered boiling water and turps on flannel to be
"put on my stomach He asked mother to stay all night,
"but she had left the children at home, and could not stay.
"Next day my mother took me home in a cab. When I
"got home. I was put on a bed till another doctor came.
"He examined me and said I must come to the hospital at
"once I started at eight in a cab We live at Enfield High-
"way and it took three hours to come as we could not come
"fast. I was operated on at five minutes past twelve.
"That was when they took me out of the ward. I don't
"remember much about the first two or three days. I am
"beginning to feel quite well now and I shall be able to
"go into service again. I have been quite happy here,
"and shall be sorry to go away. Of course I did not like
"it when I could not have anything to drink—only two
"teaspoonfuls of hot water every hour—and nothing to eat
"for three weeks, but I see now it was for my good. I
"can eat a little now My father works on the land, and
"we live in a small cottage, so I could not have had
"anything there that I had here—I mean the nursing. I
"have not had medicine here, but nursing. I believe that
"I should have died by next morning if I had not come
"up that night. I am sure I owe my life to the hospital.
"I am going next Wednesday to the convalescent home at
(Signed) R—— T——."
"Swanley.

Statement from the Hospital.—R—— T—— was brought up on March 28 complaining of severe abdominal pain. She was very much distended and the muscles were rigid. It was at first supposed that her trouble began in the appendix. She was taken to the theatre and anæsthetised. The abdomen was opened and the appendix was found to be normal. An ulcer was found in the stomach, and in the centre of this was an opening, through which food and gastric juice were coming out. The opening into the stomach was then carefully sewn up, and the abdominal wall closed except at the upper part of the incision, through which some gauze was put in to drain. The patient made an uninterrupted recovery, and leaves on May 14 for Swanley.

St. George's Hospital.

MRS. B—— (Cæsarean Section) says :

"I am the wife of a "dealer" and live in a flat at "Stockwell. I came into hospital on March 12. I went "to a lying-in hospital first, and the surgeon who "examined me there sent me on to St. George's "Hospital. I was operated on on the following day, "the small operation, and again on March 27, the "big operation. I was certainly very glad to have my "little baby alive, and I can't say enough about the "hospital. Everyone has been very kind, doctors and "nurses alike. You can put it in better words than I can. "Of course, I should not have had anything of the kind "in my own home, doctors and nurses night and day. My "husband comes to see me ; he thinks there is only one "baby, and that is ours. I think she is a big baby ; she "weighs 8¼lbs. at five weeks.

"(Signed) J—— B——."

Statement from the Hospital.—The patient, a woman aged 32, came to the hospital when 8½ months pregnant. It was found that she had a bony tumour of the pelvis which would prevent delivery of the child in the natural way, either alive or dead. There had been five "miscarriages" previously, and she was now very anxious to have a living child. Cæsarean section was therefore performed on the Thursday before Easter (last), and a healthy female child born. Both mother and child have done very well.

H—— L—— (Ruptured Spleen) says :

"I am in the employment of a business firm in South "Kensington. On the evening on which I was injured I "was going down the steps at an Underground Railway "station, when I slipped and fell forward across the "hand-rail of the staircase. The wind was knocked "out of me, and I slid down the rail on my stomach like a "child slides down banisters. The gate at the bottom was "open. It was standing open against the stair-rail, so "that I came across the edge of the gate with a crash. I "went back to my lodgings in a cab, and sent for a "*doctor, who examined me and sent me straight to* "St. George's Hospital, where I was operated on that "night. My pay is very little over £1 a week, and in my "lodgings I certainly could not have been operated on and "nursed. I am sincerely grateful for all that has been "done for me in St. George's Hospital.

"(Signed) H—— L——."

Statement from the Hospital.—H—— L——, a man aged 35, fell down stairs and injured his abdomen. Brought to hospital in an extreme condition of collapse. Immediate operation. Ruptured spleen found ; blood and blood clots washed out and hæmorrhage stopped by means of gauze packing. Transfusion performed. Recovering.

A—— B—— (Aneurysm for 16 years).—In this case there is no testimonial from the patient. The best evidence that can be supplied of what the hospital did for him will be found in the statement below, from which it will be seen that for 16 years he was enabled to return to his work after the intervals which he spent under treatment, and that the care he received mitigated to the utmost

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1901.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

possible extent, if it could not cure, the ill from which he suffered.

Statement from the Hospital.—A—— B——, a builder's foreman, at the age of 40 began to suffer from incessant cough and indefinite thoracic pains which subsequently became severe. He was first seen and admitted into St. George's Hospital in 1886 with a large aneurysm which projected through the upper part of the chest. His condition was described as "weak, ill, and hopeless." Rest, dieting, and appropriate treatment, however, caused the enlargement of the aorta to much decrease, and after nine months in hospital he left markedly improved. He subsequently was in the hospital for five other periods varying from one to six months, on one occasion for pleurisy and pneumonia, from which he recovered entirely. During the periods that he was at work the aneurysm persistently became larger but rapidly reacted to rest and treatment after admission to the hospital. The man finally died in 1901 from rupture of the aneurysm, which he had been known to have for the remarkably long period of 16 years. The usual duration of this disease may be taken as three to five years, and it is only reasonable to suppose that this unusual prolongation of life was due to the patient being able to lie up for long periods at a time and at the same time to have appropriate skilled medical attendance.

St. Mary's Hospital.

F. W. GREGORY (Wounded Leg—Amputation) says:

"I am an electrical engineer in the test room of the "British Insulated Wire Company in Lancashire. I had "run up for a few days to London at Easter for a holiday, "and was staying with my friends. I was spending the "evening with a friend, and we were fencing with some "old Spanish rapiers when I met with my accident. A "doctor was called in at once, and he did what he could, "but the bleeding kept on breaking out, and the next day "I was brought to the hospital, where I have had every "attention. Nurses and everybody have been very kind to "me. "(Signed) F. W. Gregory."

Statement from the Hospital.—F. W. Gregory. Patient had received a punctured wound in the right thigh when fencing with rapiers. He had lost a great deal of blood before coming to the hospital. He had been bandaged before he arrived, which was the day after receiving the wound. On admission he was very blanched, with feeble pulse, the skin of the thigh was torn in two places, and the main artery and vein were also torn. The wound was cleaned up, the artery and vein were ligatured, and transfusion was performed. Two days afterwards gangrene was commencing in the foot on account of the deficiency of blood, and it was necessary to amputate the leg. Since then he has made fair progress towards recovery.

J. WALKER HANNA (Amputation of Leg) says:

"I am a submarine cable engineer. I went out to the "West Indies from College. I fancy what I have suffered "from is the result of a fall. The surgeon who operated "can speak as to what it was. He has been especially "kind and taken a great interest in my case, and his skill "and the good nursing I have had has brought me round. "I came home 5,000 miles, in great pain all the way, in "order to be operated on. It seems a providential thing "that I should have done so, for my ship was the *Grappler*, "so that I should have been lost in the Martinique "disaster with all the rest of those on board the ship if "I had not come home on account of my leg.

"(Signed) J. Walker Hanna."

Statement from the Hospital.—J. Walker Hanna. Treated for abscesses in the leg in the West Indies. On admission to the hospital he was found to be suffering from sarcoma of the tibia, necessitating amputation of the leg. Amputation was performed and the patient is doing well.

St. Thomas's Hospital.

HENRY DAMPIER (Abscess of Liver) says:

"I am a postman. I was in the merchant service for "two years, and in the army for 11 years. I served in "India, Burma, China, and Africa, in the Northampton "Regiment. I was called up as a reservist for the "Transvaal War, and was with Lord Methuen's column at "Magersfontein, Belmont, Graspan, and Modder River, "and was invalided home last July, with abscesses on the "liver. Since then I have been in a convalescent home "and have done some soldiering; I went home on working "furlough and started at my old employment, but I have "had it all the time more or less with liver trouble, and "was laid up for three months previous to coming into St. "Thomas's Hospital. I was sent up by my doctor at "Uxbridge. I have been in the hospital a month, and "was operated on the 25th of last month, and since I have "been operated on I have felt a great deal better. I have "been treated very well by doctors and nurses. I cer"tainly could not have got on without coming into a "hospital. I could not get about. I was hopeless. Now "I shall be able to get back to my work, and I hope to be "at it before very long. "(Signed) Harry Dampier."

Statement from the Hospital.—The patient, aged 28, was admitted suffering from abscess of the liver. He had been a soldier, and had suffered from dysentery and enteric fever in South Africa in February, 1901. He had an abscess of his liver opened in March. Later he returned to England convalescent and worked as a postman. Subsequently he began to suffer from aching pain in the abdomen and on the right side, and from other symptoms. He lost weight and flesh, and was incapacitated from work. He was operated on in St. Thomas's Hospital on the 16th of April, 1902. Gradual convalescence has followed.

ALFRED PAUL (Intestinal Obstruction) says:

"I am a hair-dresser. I have been in hospital 15 "weeks next Saturday. I was at home for some time but "could not get well. I have not been right since last "October. Since I have been in I have been operated on "four times. It was impossible that I should have been "operated on at home or nursed there. How have I been "treated in the hospital? Well, I could not have been "treated better. I wish I could make the hospital a "present, but I cannot afford to do so.

"(Signed) Alfred Paul."

Statement from the Hospital.—The patient (aged 37, with a wife and five children) had been healthy all his life and temperate. Three weeks before coming to the hospital he complained of abdominal pain, vomiting and diarrhœa, which continued until three days before admission, the obstruction became absolute, and on admission he had fæcal vomiting. He was operated upon on Jan. 25, 1902. The cæcum came out of the wound and burst, because it was so highly distended. After this operation he was very ill for some days, and on Feb. 22 he had another attack, and another operation. He was again very ill, but recovered. April 5 an anastomosis was made to help to close the artificial anus. April 26 another operation was performed for closure of the artificial anus. The patient is to be discharged and to come in again.

This is another instance of the benefit conferred by hospitals, and hospitals only, upon patients. In such a case the continued supervision of surgeons and nurses is necessary, while there is every convenience for immediate operation, should necessity arise, under conditions impossible except in a hospital.

G—— P—— (Appendicitis and General Peritonitis) says:

"I work at an iron factory. I fancy I strained myself "lifting heavy weights at my work, and pushing a truck "up a hill. I got very bad and in great pain, and couldn't "stand the pain, and thought it best to come to the "hospital. I live with my father, a porter, so could "not have been cured at home. I have been treated very "well in the hospital, and am very glad I came there.

"(Signed) G—— P——."

Statement from the Hospital.—The patient, aged 17, an errand boy, had been a perfectly healthy boy. Two days before admission he had been taken with sickness and pain in the abdomen. He was operated on immediately, within an hour of his admission. General peritonitis was found and the appendix was gangrenous. It was removed. The abdominal cavity was washed out with salt solution, and the abdominal wall sewn up. He is now convalescent. Cases of this kind never recovered until quite recent years. They belong to a class that can be treated much better in a hospital than in the home even of wealthy patients, because in private practice it is often difficult to wash out the abdomen properly, as all conveniences are absent.

University College Hospital.

MISS B—— (Strangulated Hernia) says:

"I am a Visiting Sister at L——, a deaconess, resting "for a few months until I get strong. I came to London "just for a few days' holiday. I was up but two days when "this happened through a fit of coughing about six o'clock "in the morning at the house of my sister. A doctor was "called in, and he, of course, could not do anything by "himself, but seeing what was the matter he got me a "paper at once and I was taken into the hospital. I had *nothing to do with it. I did not care what they did* with me so long as they cured me. At the hospital I was operated on at once, and am now getting well as fast as ever I can, and hope to go home at the end of next week, but I have to promise that I shall not do any work for six weeks. If there had been no hospital to go to I could not have lived. I, of course, could not afford surgeons and nursing As far as what I had the matter with me, I cannot tell you how bad I felt, and I should, I know, have died if I had not been attended to. I cannot speak too highly of the hospital and of my treatment here by nurses and doctors alike. Everything is very comfortable. "(Signed) M—— B——."

Statement from the Hospital.—A case of strangulated hernia. Operated on in the hospital Recovering.

FRANK ORCHARD (Diphtheria, Tracheotomy). MRS. ORCHARD, Mother of Frank Orchard, visited at her home, says:

"My little boy I took to the hospital in March, 1901, with the diphtheria when he was very bad, nearly dying. He was better that morning, but in the afternoon he came over bad, and I ran directly with him to the hospital, and he was operated on directly, and was in there seven months. He was given up, so that I could go at any time to see him. My husband has been *there, up to Fourteen Ward*, as many as three times a day. I am very thankful for the hospital, very thankful for their kindness towards him. I was often there, and I know he had every kindness from the nurses and the sister. My husband is a porter at a warehouse, and we certainly could not have afforded doctors and nurses; there is no doubt about that. My little boy has been in there again since with the pneumonia.

"(Signed) MRS. ANNIE ORCHARD,
"110, Whitfield-street."

Statement from the Hospital—FRANK ORCHARD, aged 1½ years, 110, Whitfield-street, was admitted to the hospital on Feb. 6, suffering from diphtheria, which affected not only the back of the throat, but also the windpipe, the upper part of which was almost completely blocked with diphtheritic membrane The child was in a condition of great prostration, and could inspire a little air into the chest only with the greatest difficulty; the veins of the neck were greatly distended and the face livid. If no operation had been done for his relief he would assuredly have died in a short space of time. Immediately on admission the windpipe was opened below the seat of obstruction, and the patient at once relieved from his distress. A tracheotomy tube was introduced into the wind-pipe, and the child put to bed in the diphtheria ward. Diphtheria antitoxin was *administered, and steam sprays used for the throat.* For

the first few days, as the child was troubled with continuous vomiting, feeding by the bottle was resorted to, and as the temperature frequently rose to 105°, wet packs were employed in order to reduce it. Within 48 hours, as is usual in cases treated with antitoxin, the membrane began to separate from the throat and windpipe, and, as it was coughed up, frequently stuck on its passage, thereby rendering the child in imminent danger of choking. Each time this occurred the doctor was sent for and he introduced a pair of long curved forceps into the windpipe and removed the membrane. This went on for four days, the doctor frequently being up twice in the night to attend the child. When all the membrane had been coughed up and the windpipe was clear, a new danger was presented to the child, as it was found that on removing the tracheotomy tube he still could not breathe through the larynx. Attempts were therefore made to assist the child in doing without his tube by passing an intubation tube down the larynx into the wind-pipe, so that he could breathe in the usual manner. The child continually coughed the tube up, and then showed signs of choking. This caused the nurses considerable anxiety, as the doctor had to be sent for each time to replace the tube. In a few days the child developed a severe attack of pneumonia, and the tracheotomy tube was replaced, as he was not in a fit condition to undergo intubation. On April 28 the child had perfectly recovered from the pneumonia, and attempts were again made to get rid of the tracheotomy tube by substituting intubation, and by June 1 the child could breathe quite well without either intubation or tracheotomy tube, and was discharged cured on June 20. The child was readmitted to the children's ward on July 25, as he had contracted an attack of broncho-pneumonia, and was again discharged cured on Sept. 10.

Westminster Hospital.

GEORGE BROWN (Compound Fracture of the Leg) says:

"I am a labourer. I clean engines at the hydraulic. I "was using the lift; I went to step in again where I had "left the lift and it had been moved by someone, and I "fell down a fall of 42 feet. I was insensible. I came to "in the hospital, where my leg is now getting well. "Everybody has been kind to me in the hospital and I "have had everything I wanted. If there had been no "hospital I don't know how I should have got on. The "same leg was run over by a brewer's dray and broken "when I was a little boy, and I was then taken to St. "Thomas's Hospital. "(Signed) G. BROWN."

Statement from the Hospital.—GEORGE BROWN, aged 19, was brought to the hospital, having fallen down a lift, 42 feet. There was found to be a bad compound comminuted fracture of the tibia; this was operated on and set. The result is a good leg. In earlier days this would have been a case for amputation.

A—— G—— (Perforation of the Stomach and Peritonitis) says:

"I am a domestic servant, and was out in service when "I was taken ill. I had been in a situation three weeks. "My mistress sent for a doctor for me, and he ordered me "at once to the hospital. I was operated on at once, and "now I am very much better. I have been treated in the "hospital very well in every way. I have no home unless "I make it myself, and I could not have been cured "except in a hospital. "(Signed) A—— G——."

Statement from the Hospital.—A——G——, age 36. Patient was in good health up to evening of April 27, when she was suddenly seized with acute pain in the stomach with violent sickness. She was sent in to hospital and found to be suffering from acute peritonitis. An immediate operation showed the presence of a rupture of the stomach, this was sewn up, and the contents, which were soiling the cavity round the stomach, were carefully washed away. The abdominal wall was then sewn up. No dangerous symptoms supervened, and recovery may now be called complete. Such cases are exceptionally dangerous, and require immediate and skilful treatment to save life.

E—— D—— (Had not walked for 17 years) says:

"I am an orphan. My mother has died since I came to "the hospital. I was unable to walk for 17 years. It "was 17 years last March that I think I overdid my "strength, I also had a great fright through a girl, and I "seemed to fail after that. I was under lots of doctors "at Greenwich, where I lived. I was sent here and I "have been here three months. I am now able to walk "about a little and I hope I shall get to walk quite well. "But for the hospital I should never have been able to "have the treatment. It seems so strange to be walking "about after all that time. I was always so sick too. I "could not keep anything down. I am not now. I have "been quite happy and comfortable in the hospital. "Everyone has been very kind.

"(Signed) E——. D——."

Statement from the Hospital.—E—— D——, age 37. This patient has been blind since soon after birth. At the age of 23 she was laid up with weakness of the legs and since then she had been unable to move from her bed. She was thin and weak on admission, and on examination no evidence of any incurable nerve disease was found. Treatment by massage, electricity, isolation in special ward, with special nursing and diet, with the result that she can now walk across the hospital and gains weight and health every day.

GRATEFUL EXPRESSIONS TO THE NURSES.

The monotony in the statements that I have collected from the lips of hospital patients is owing to the manner in which their views have necessarily been obtained. Quite late in my inquiry a chance remark by a Sister in one of the largest hospitals suggested to me that there might be "testimonials" more spontaneous, more varied, more absolutely free from restraint or suggestion, than those I was acquiring. I refer to grateful letters written by patients after leaving the hospital to the sisters and nurses who have tended them.

As I have only asked for these in one or two instances, I do not name the hospitals to which they were sent. As they were written without any thought of publication, all names and sources of identification of the patient are also suppressed. I can only say confidently that I could have had hundreds of them had I desired it, but their genuineness must rest for the above reasons on internal evidence, and beyond this they must speak for themselves:—

DEAR MADAME,

I beg to say my husband arrived home quite safe Friday evening, "I disire to return you my most sincere thanks for your kindness to him, he is never tired of telling me how very kind the Sister's and nurse's were to him when hé was in Hospital, he miss your skilfull treatment very much, I do my best to dress him, but only this morning he said if only the Sister could walk in, how soon she would make me comfertable," I am so dreadfully nervous and so afraid I should hurt him, I think that is ware the trouble come in, should you Madame or any of the Lady's visite this neighbourhood at any time I should be very happy to give you a most hearty welcome to my humble home, my husband desire to be kindly remembered to the dear Sister's, also to the nurse's that were so kind to him, he is going on nicely but feel the need of the belt very much and will be very glad when it come, again I thank you Madame for your great kindness to my Husband also for forwarding the letter I sent him.

I beg to remain Madame yours very gratefully F. L.

May 10th, 1902.

Dec. 22nd, 1901.

SISTER,

I write these few lines to you to let you know that I am alrite from the time as I was in —— Hospital under your care. I was No. 16 in your Ward I am the man as they did call Old Taffee because I was from Wales I am a Collier and I was there to go under Opperation with a Henia I was there Last March I was with you a Month and I am alrite from it now it was Dr. —— was my Doctor and Dr. —— Please to tell them from me I am thankful to them for Curing me and I am Thankful to you Sister and all the Nurses how you treated me and I thank you how you treated me on Good Friday with the Tobacco you give me so I enclose a Order for 2s. for you to buy some little toys for some of the boys you got in there for to enjoy themselves over Christmas and I hope as you and all the Nurses will spend a Merry Christmas and a Happy New Year So no more from your Obedient Patient. A. B.

Comenly Called Old Taffee Please send a note back Sister.

The Royal Sea Bathing Hospital.

Dear Nurse F——,

You will I am sure think that I have got so interested in the sea and the sea-breezes that I have forgotten to write and let you know how I am getting on. It is beautiful down here and the air is grand. You could soon tell the difference as you came along in the train how nice and fresh the air is. I am glad to say that I have improved wonderfully, I hardly know myself like, especially my nose as the sun, sea-breezes, salt water as been taking a mean advantage of it by taking off all the skin or nearly all. I am still taking wapping big spoonfuls of jam, treacle and hope 25 is still doing the same. The wound has very nearly healed up, I have a hot salt water bath every day and that has done me a lot of good. I have got a good old pal and he has jam too, so we are a jammy lot altogether. We go out on the sands three times a week, which has been my first experience of crab-hunting or I should say pearl-shell hunting, but the first day I did not know oyster shells from pearl shells, but I think I know them now. I am going to bring enough sea air back to last me two or three (years) or weeks. Of course I don't want to get to work. I hope that lazy 24 and 5 has got up by now, I am sure they need to be separated, also 16 tell him he is to get up by the time I come back. Most of the patients sleep out all day and night. I slept out one night and that was enough, I didn't get half cold. Although it is been much warmer lately and we have had a few April showers yesterday and to-day of course they are late coming in May. Now I must close I feel as if I can never repay all that has been done for me at the Hospital by the Drs., Sister F——, the nurses and yourself. It is just tea time so Goodbye.

I am Gratefully,
W ,
one of your patients.

April 7th, 1902.

Dear Sister F——

I hope you got the few Primroses on Saturday? My little Girls Picked them and wanted me to send them.

I have so often spoken of your kindness to me to them they were so Pleased to send them. I am enclosing P.O for 4/- If you would Kindly Accept it to get a few flowers or any little thing for the Ward.

I am Pleased to say I am getting on very nicely begin to feel quite myself. Thanks to the treatment and kindness Received at the Hospital,

I beg to Remain
Yours Very Gratefully
X. Z.

ALL MUST HELP.

The lessons of the inquiry undertaken for us by our Special Commissioner are so obvious as to need only a few words of exposition. As our Supplement is written frankly with a view of arresting the attention of the public, popular and colloquial language has been employed in the medical and surgical statements from the hospitals. With regard to the choice of cases the only difficulty experienced arose out of the superabundance of material—in every institution, and in every ward of every institution, lay men, women, and children testifying to the good work of the metropolitan hospitals by their improvement under the treatment that they were undergoing. By the invaluable assistance of the staffs of the hospitals, of the resident medical officers, and of the nurses, our Special Commissioner has been put into communication with numbers of patients suffering from accident or disease where the value of hospital treatment was typically evident—where, in fact, without hospital treatment the patient would either have died or have been, in all probability, damaged for life. Of these cases we have only to say that their counterparts present themselves daily at the doors of all our medical charities.

To our usual readers the significance of the group of cases chosen will be apparent, but a few words should be added concerning the selection for the benefit of our lay readers. Firstly, these cases are detailed in proof of the great scientific skill exercised as a matter of daily routine in the operation theatres of our hospitals. Such operations as the suture of a ruptured spleen or the excision of a cerebral tumour can only be undertaken in the favourable circumstances prevailing in hospital practice. The same may be said of the procedure necessary to save life in cases of ruptured pelvis or of double amputation. Cases of operation to relieve a strangulated hernia tell a somewhat similar story. But they do not rank as surgical curiosities; their importance lies in their extreme frequency. Here a surgical operation is required by a large number of the working classes which could never be undertaken in their own homes without grave risk, which in the hospitals is remarkably successful, and which is absolutely necessary to save life. It is hardly an exaggeration to say that if hospitals, not only in London but in the civilised world, existed only to furnish skilful operative procedure for strangulated hernia among the poor they would be amply justified in appealing for public support. A case of concussion and one of aneurysm teach a different lesson. Here we see the value of the hospital in providing a rest cure either of short or long duration. The happy result of an operation for varicose veins is a good example of the part played by expert surgery in moulding a man's future—the story is one that hundreds of lads could cap, and the same may be said of the case of the infant saved, by the administration of antitoxin, prompt

tracheotomy, and assiduous nursing, from death from diphtheria.

Surely the places where such things are done ought not to have to beg for their existence! Surely it is wonderful that there is not an absolute competition among the rich to place these splendid charities on a sound financial basis.

Such is our appeal on behalf of the Metropolitan Hospital Sunday Fund for the Coronation year. The population of London is increasing by leaps and bounds, which every year makes the metropolis more distinctly the centre to which the empire resorts, so that the institutions of London are regarded as serving the necessities of a world rather than of a city. But while the population of London becomes larger the income of the Metropolitan Hospital Sunday Fund, as far as it is drawn from the people rather than from individual donors of big sums, remains stationary. This should not be. We have taken it for granted that no words are necessary to bring home to our readers the terrible misery which sickness means to the poor man and poor woman. The incapacity of the breadwinner to earn his wages at once places the family of the poor man within a measurable distance of starvation. That little distance would be immediately crossed if the hospital did not open its doors to the sufferer. But, alas, many hospital beds are closed and many unfortunate people have to be refused the shelter which means so much to them and so much, perhaps as much, to their families. It is the lives of the poor for which we are pleading.

The rich should give out of their superfluity, and not only because they are rich, but because they are themselves directly benefited by the hospitals. For without our hospitals the benefits which the rich derive from skilled medical attendance could not be theirs.

The poor should give out of their poverty. They need no reminding as to what the hospital means to them when they are sick. But they need much reminding as to the value of little gifts, or the Metropolitan Hospital Sunday Fund would not stand at the annual figure of £40,000.

To the benevolent man no scheme can commend itself as more worthy of his assistance than a fund to benefit his suffering and poorer brethren.

In the eyes of the practical man no less than in those of the benevolent the Fund should, nay must, find favour, for it represents order in the distribution of charity.

To all social grades, to all creeds, and to all casts of thought, the Metropolitan Hospital Sunday Fund must appeal as a noble charity, splendidly directed, economically managed, and equitably administered. That it may meet with support worthy of its merits is our most earnest hope. What nobler way of commemorating Coronation year can there be than by making that year the first in which the Metropolitan Hospital Sunday Fund receives £100,000?

And let us again remind our readers that if £80,000 can be raised in the churches and chapels, an anonymous friend of the Fund, whose previous generosity has been splendid, will at once give the £20,000 necessary to bring the total to the coveted sum.

Audited and found correct, this 20th day of November, 1901.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall street, E.C.

⁂ In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

Printed and Published by the REGISTERED PROPRIETORS of THE LANCET, at 423, Strand, W.C., and Nos. 1 and 2, Bedford street, Strand, adjoining.

the degeneration of the nerve is of rapid, and not only of rapid but of irritative, character the muscular fibres undergo a similar change, a more irritative degeneration, a quick destruction, with granular and fatty degeneration and a rapid disappearance of all electrical excitability. These facts indicate a close vital relation between the muscular and nervous structures—a relation it is well to remember.

Of the many forms of abiotrophy in the nervous system, perhaps the most striking is one of which these spinal motor neurons are the seat. It is rare but it has been observed many times.[7] It commences soon after they have attained structural completion, about the end of the first year of life, and progresses so rapidly as to cause almost universal paralysis and death at the end of the fifth or sixth year. It occurs in families as well as in isolated cases and in both sexes, and is thus clearly due to a congenital defect of vital endurance. After death there is found almost complete degeneration of the motor cells of the spinal cord, with very little change in the white columns, total degeneration of the anterior roots and of the motor fibres down to the muscles, and extreme degeneration of these. It has, indeed, been conjectured that both the motor neurons and the muscles suffer simultaneously; whether it is so or not we cannot say, for the affection of the motor neurons is sufficient to account for the muscular changes. It is quite certain that the degeneration of the motor nerves is not a consequence of the muscular atrophy. In extreme idiopathic muscular atrophy the nerves may be unaffected. A striking proof of this is afforded by a case which was observed by Duchenne and published by him when the patient was nine years old; it was afterwards observed and described when the patient was 28 years old by Landouzy and Déjerine. The patient died when he was 36 years old, but the thorough pathological examination that was made has only lately been published.[8] In spite of extreme degeneration of a large number of muscles of limbs, trunk, face, and neck the motor-nerves and spinal motor-cells were absolutely normal.

But this abiotic infantile atrophy presents one remarkable feature: the affection begins in the muscles of the hip and thigh and trunk, and thence extends, reaching last the extremities of the limbs, which suffer first in the ordinary form of spinal atrophy. It is a feature presented both by muscular abiotrophy and by this remarkable neuronic form. Such common features are noteworthy as links between the muscular and nervous systems. A similar form of neuronic atrophy is occasionally met with in families in later childhood and early adult life; the later the onset the greater the resemblance to the common type. In some forms the cerebral motor neuron also suffers, the upper segment of the motor tract, as it does in the atrophies of later life. The isolated decay of this cerebral motor neuron is also met with in early adult life as an abiotic degeneration of the lateral columns—the pyramidal tracts. It is manifested by spastic paraplegia, coming on often without any exciting influence and sometimes in several members of the same family.[9] Occasionally the malady has followed some influence, such as an acute disease, which would depress the nutritional vigour of the whole nervous system but has an enduring effect only on structures whose vitality is defective and might soon fail without this influence.

I have here to show you an example of such abiotic spastic paraplegia. It is the more instructive because it is isolated; such sporadic cases are far from rare. Their nature is often not discerned, because it is not suggested as it is when other members of the family suffer. The patient is 20 years of age and his symptoms commenced gradually about three years ago without any cause to which they can be attributed. There is no suspicion of inherited or acquired specific disease. He has weakness of the legs, with some spasm, excessive knee-jerk and foot-clonus, with no change in sensibility or girdle pain. He has also some unsteadiness, suggestive of slight failure of the posterior columns. The abiotic nature of the case is confirmed by the fact that another system of fibres is also failing. He has atrophy of the optic nerves which also has developed gradually and which presents the aspect of simple atrophy. The simultaneous occurrence of such degeneration in two neuronic systems at this period of life leaves no doubt of its nature.

The optic nerves frequently suffer from abiotic wasting. Many groups of cases are on record in which several members of the same family have become blind, usually between the ages of 15 and 25 years, from a slow failure of the nerve fibres, progressive in spite of treatment. A full account of these cases has been given by Dr. S. H. Habershon.[10] This progressive course places their essential nature beyond doubt; yet it is obscured by the fact that the early stage has very often been accompanied by symptoms of retro-ocular neuritis with even slight signs of it in the disc. There has often been a central scotoma indicative of an "axial neuritis." The change, moreover, has often been preceded by a cause believed to be capable of inducing neuritis, especially tobacco-smoking, or in the case of women by some acute disease. We may understand this fact better, I think, if we remember what I said just now regarding the independent energy of the interstitial overgrowth when it has been set up by degeneration of the nerve elements. Remember, also, the great amount of interstitial tissue which is formed in the optic nerves even in primary tabetic atrophy. Tobacco amblyopia is apparently due to an axial neuritis, and this gradually ceases and its effects pass away when the cause ceases to act. But the loss of sight, in the case I am now speaking of, goes on steadily increasing after tobacco has been given up. It goes on as by a progressive atrophy of the nerve elements, not by an increase of the signs of neuritis, showing that the toxic agent was only the exciting cause of the process really due to an inherent defect of vitality. In those who are not smokers the toxin of an acute disease seems sometimes to have acted also as an excitant. We know that that of scarlet fever may cause pronounced neuritis. The difficulty is to understand that optic abiotrophy, wasting of the nerve-fibres from defect of vital endurance, should apparently begin by interstitial inflammation. Let me remind you of what I have just said regarding this interstitial process. Secondary as it seems it may be simultaneous in a very absolute manner. There seems to be a solidarity in the nutritional energy of the two tissue elements, the neural and neuroglial, and the tendency to overgrowth of the latter may be actually simultaneous with the tendency of the life of the former to cease. The tendencies are in the opposite direction, but they may be coincident results of the same vital condition. If so, we can understand that the trophic tendency of the interstitial tissue may cause it to respond with energy to a toxic influence which can act upon it and that thus retro-ocular neuritis the effect of a toxic agent may concur with the very commencement of the abiotic wasting of the nerve elements, and that its special symptoms may even seem to lead the way.

It is not a little curious that in the patient before you, with abiotic spastic paraplegia and optic atrophy we find indications of the same associated process that I have described. As far as its course and the ophthalmoscopic appearances are concerned it seems to be a primary simple atrophy of the optic nerve. His acuity of vision is reduced to one-tenth. The fields present a peripheral restriction, but no central defect in the fields for white can be detected, even with a small object. Yet it is different with the colour fields. My clerk, Dr. Finny, finds a well-marked central scotoma for both red and green (see accompanying chart). It is irregular in outline but extends to an average of about 10° from the fixing point and in one eye to 20°. This, of course, led to an inquiry regarding tobacco-smoking and we learned that he had been accustomed to smoke as much as half an ounce of shag tobacco a day. Thus this case agrees with those of isolated optic abiotrophy which I have mentioned in presenting slight symptoms of axial neuritis and in the fact of this exciting cause. But it presents the progressive tendency and also the peripheral restriction of the field and the aspect of disc met with in ordinary atrophy, while its abiotic nature is shown also by the coincident affection of the cerebro-spinal motor neurons. The spinal symptoms in this patient, the spastic palsy and unsteadiness due to atrophy of these neurons and those which conduct to the cerebellum, are such as often form part of the best known abiotrophy, Friedreich's disease, the so-called "hereditary ataxy." The latter name is

REPORT OF

THE LANCET

Special Commission

ON

GLYCERINATED CALF VACCINE LYMPHS:

GIVING THE NUMBER AND NATURE OF THE "EXTRANEOUS" BACTERIA FOUND IN THE COMMERCIAL VACCINE LYMPHS.

OUR investigations into the purity and activity of vaccine lymphs undertaken by us two years ago have been renewed and continued.[1] As on a former occasion, all the vaccines on the market have been examined as well as a sample of the Local Government Board lymph In addition to these one obtained from an Italian source has also been dealt with. In all cases these lymphs have been examined bacteriologically and in most some additional information has been obtained as to their vaccinal activity The net result of our inquiry is to confirm in all essentials our previous report.

JENNER INSTITUTE FOR CALF LYMPH,

73, CHURCH ROAD, BATTERSEA, LONDON, S.W

(AGENTS ALLEN AND HANBURYS, LIMITED, PLOUGH COURT, LOMBARD-STREET, LONDON, E.C)

Received three tubes of aseptic glycerinated calf lymph, No 3210, on Jan. 17th, 1902. This lymph is said to be "prepared strictly in accordance with the methods advocated by Dr S Monckton Copeman." Agar and gelatin plate cultivations were made on Jan 22nd and an anaerobic glucose formate agar shake cultivation was made on the same date The results obtained were not so good as were those obtained on a former occasion The agar plate was overgrown with organisms at the end of 24 hours, there were many rapidly growing surface colonies with crenated margins and with a peculiar greenish tint characteristic of the plate as a whole. On examining these colonies some were found to be grey cloudy growths with dark brown centre, crenated margins, and wrinkled surface. Under the microscope these colonies were seen to consist of collections of thick rods, three or four times as long as broad, arranged side by side, with rounded ends and often containing spores. The second series was made up of rapidly growing, very thin, proteus like growths with a slight bluish or greenish tinge. The long finger like processes growing out from the margin were clubbed and usually considerably thicker than the main body of the growth Rods similar to the above but offering no evidence of spore formation were also present. Other colonies of a third series were made up of staphylococcus albus (under the microscope, however, these organisms appeared to be somewhat larger than ordinary staphylococci) On the gelatin plate at the end of the eighth day there were about 680 colonies, only one of which liquefied the gelatin. Some of these colonies, growing very rapidly, had crenated margins. Amongst these were found isolated cocci (staphylococci) a very few minute bacilli, and a number of colonies of torulæ. In the glucose formate agar tube an enormous number of very fine colonies made their appearance in the depth of the agar, they were so numerous, indeed, that they were uncountable, no gas was formed. On the 29th a second series of cultivations—from vaccine tubes No. 3459—was made in agar and in agar heated to 60° C. for one hour in order to get rid of all but spore-bearing organisms In the agar plate 784 colonies were developed resembling those found on the earlier plates, whilst in the specimen heated to 60° C for one hour not a single colony was developed.

ANIMAL VACCINE ESTABLISHMENT,

UNDER THE SUPERVISION OF DR. CHAUMIER OF TOURS, AND 10, RUE DE LATRAN, PARIS.

In the form of liquid glycerinated pulp, concentrated and reinforced prepared under the most minute antiseptic precautions

Two tubes at 1*s* 3*d*., 25 vaccinations each, No 6, date sent out Jan. 17th, 1902. Agents for Great Britain, Messrs Roberts and Co., 76, New Bond street, London, W This lymph when mixed with broth appears to be slightly granular and as seen in the tube has a faint pink tinge. On Jan 23rd the vaccine in the tube was mixed with three cubic centimetres of broth, one cubic centimetre of this broth was then added to agar and a plate culture was made, one cubic centimetre was plated out in gelatin, and one cubic centimetre was added to a glucose formate agar tube. On the agar plate over 16,000 colonies developed. Some of these were large, grey, moist, opalescent colonies which were made up of short plump rods with rounded ends, these rods contained both spores and aggregations of protoplasm. Other colonies consisted of soft, slimy, opaque growths, with a sharply outlined slowly advancing margin, these were made up principally of small staphylococci (*? microcoque porcelaine*[2]), amongst these, however, were a few large rods with somewhat truncated ends. On the gelatin plate only 34 colonies developed, most of these were staphylococci. In the glucose formate agar tube thousands of colonies of very unequal size had developed. A portion of the second tube was used for the purpose of determining the presence or absence of resistant spore-bearing organisms. A definite quantity was added to agar culture medium, this was heated to 60° C for one hour, a plate was then made. Only a couple of colonies made their appearance.

(3)

FERRIS AND CO., BRISTOL.

Six half tubes of "selected glycerinated calf lymph," bearing reference No. O. 573, three tubes for 2*s* 6*d*, posted from Bristol on Jan. 17th, 1902. The lymph is clear and has a faint brown tinge. On Jan. 23rd an agar plate, a gelatin plate and a glucose formate agar tube were made. In the agar 47 colonies developed one of these a small colony with crenated edges had a reddish-green tinge. This did not grow rapidly, it was made up of rods with spores or aggregations of protoplasm. These rods were arranged irregularly side by side, three or four times as long as broad, with rounded ends. Most of the colonies consisted of typical staphylococcus albus but a few of them of very large cocci, single, in short chains, or in groups On the gelatin plate only a single colony like that of the bacillus coli communis (translucent with a series of radiating processes at the periphery, the margins being crenated and thickened) made its appearance. On microscopical examination, however, this colony was found to be made up of staphylococci. In the glucose formate agar tube were thousands of minute colonies, which however, like those already found in other specimens examined, did not make their appearance for a number of days, so that at first the tubes appeared to be almost sterile; when, however, the tubes were examined on the tenth or twelfth day the number of colonies was enormous. In a cultivation examined for spore-bearing organisms not a single colony could be found; all the organisms had been destroyed at a temperature of 60° C. maintained for one hour.

FAULKNER'S PURE RELIABLE GLYCERINATED CALF VACCINE LYMPH,

16, ENDELL-STREET, LONG ACRE, LONDON, W.C.

This lymph is slightly opaque and has a faint red tinge; "Source, W.F.H., 2" (three tubes for 2*s.* 6*d.*). It was not dated but arrived on Jan. 18th, 1902. On the 23rd the usual cultivations were made. On the agar plate about 200 colonies developed. Some of the colonies were white, pearly, or glistening and opalescent. They were made up principally of faintly stained long thin non-sporing rods with square-cut or slightly rounded ends. A second series consisted of spreading ground-glass-like colonies with fairly sharply-marked slightly-crenated margins; these colonies were made up of well-stained rods, three or four times as long as broad, with rounded ends, placed side by side fairly regularly; the protoplasm was collected into little aggregations but no distinct spores could be made out. Most—340—of the colonies growing in gelatin resembled the staphylococcus albus, both to the naked eye and microscopically. There were two liquefying colonies and 15 moulds. In the glycerine formate agar tube there was a well-defined potato bacillus on the surface of the medium: some hundreds of anaerobic colonies made their appearance in the depth of the medium. In the agar heated to 60° C. for one hour only six colonies developed on the plate.

(5)

DR. WARLOMONT'S GLYCERINATED CALF VACCINE.

AGENTS: MARKT BROS. & CO., 38 & 39, BEECH-STREET, BARBICAN, LONDON, E.C.

No. 8, date 17/1/02; three half tubes at 1*s.* This is a clear lymph contained in yellow tubes. An agar plate made on Jan. 22nd contained 112 colonies, mostly discrete, white, moist, and semi-opaque, consisting almost entirely of the staphylococcus albus. A gelatin plate made on the same date developed 28 colonies which consisted almost entirely of encapsuled cocci and a number of soft "painty"-looking colonies which were found to be yeasts. A comparatively small number of anaerobic colonies—from 40 to 70—grew in the depth of the glucose formate agar but there was no growth on the surface. There were no spore-bearing aerobic organisms.

ESTABLISHMENT FOR VACCINATION WITH CALF LYMPH,

186, MARYLEBONE-ROAD, LONDON, N.W.

Three small tubes, No. 12,185 (price 2*s.* 6*d.*), sent by Dr. Charles Renner, 17/1/02, with the request, "Please use it as soon as possible." On Jan. 23rd an agar plate was made. At the end of six days 2000 colonies had made their appearance, most of these consisting of staphylococcus albus of a somewhat small variety. In glucose formate agar there were thousands of tiny brownish colonies growing deep down in the nutrient medium but none on the surface. The anaerobic colonies appeared to be made up of thin short rods and a number of cocci. In the tube heated to 60° C. for one hour there were three colonies, all of them spore-bearing. One, a proteus-like colony, spreading rapidly, was made up of short rods with rounded ends, the second, like the bacillus figurans, consisted of larger thicker rods, and the third, a very small round colony, consisted of curved rods and threads. A gelatin plate made on March 15th from a second sample, No. 82,610, vaccine of date 13/3/02, contained at least 1500 organisms, a single mould, and 30 or 40 liquefying organisms. Most of the organisms which did not liquefy the gelatin were of one species—the staphylococcus albus. A few of the colonies were yeasts and a number were short, delicately stained rods very like the bacillus coli communis; these were small, fairly prominent, transparent colonies; some of the rods had a distinct curve and some were C-shaped; the bulk of the organisms present were single cocci or staphylococci.

THE ASSOCIATION FOR THE SUPPLY OF PURE VACCINE LYMPH,

12, PALL-MALL EAST, LONDON, S.W.

Two tubes, 4*s.* (in orange-coloured or amber glass), were received on Jan. 18th, 1902. These were dated 17/1/02 and marked: "To be used before 2/2/02. No. R. 822." This lymph is slightly opaque, very faintly blood-stained, and very granular. On the 23rd, or six days after it was sent out (one of these tubes was divided into three portions, the contents of the tube being placed into three cubic centimetres of sterile broth, the whole thoroughly mixed, and one cubic centimetre of the mixture used for each experiment), a gelatin plate was made with a third of the contents of one of these tubes. After four days 86 colonies had developed; most of these colonies were staphylococcus pyogenes albus or some organism very closely resembling and nearly allied to it, a yeast, and an iridescent and translucent colony composed of staphylococci or rather chains of diplococci. On the same day a similar quantity of this vaccine was mixed with agar and a plate was poured. On the 24th this plate was crowded with an uncountable number of organisms consisting principally of staphylococci and diplococci in chains, there were, however, in addition to these a number of rods with rounded ends divided into three or four segments, some of these rods contained spores, in others rapid vegetative division was going on. A similar quantity of vaccine mixed with glucose formate agar gave thousands of small anaerobic colonies, especially in the depth of the tube, by the ninth day, though on the first day only about 300 colonies, facultative anaerobes, could be seen in the upper part of the medium. At a later date, Feb. 10th, a second sample, No. 1217, was obtained and heated to 60° C for one hour When examined two days later 30 colonies had developed in this medium, some of these had crenated margins, were opaque white, with a brownish or yellowish tinge On microscopical examination these colonies were found to consist of banded or beaded bacilli almost like short diphtheria bacilli, but on more careful examination they were found to contain well-marked spores It should be noted that here, as when last this specimen was examined, the number of organisms growing on the agar plate was out of all proportion to the number of those growing on gelatin.

GLYCERINATED CALF VACCINE LYMPH FROM THE INSTITUT DE VACCINE ANIMALE, PARIS.

DIRECTEURS L. CHAMBON AND DR. ST. YVES-MÉNARD.

AGENTS FOR THE UNITED KINGDOM AND COLONIES THE MEDICAL SUPPLY ASSOCIATION 12, TEVIOT-PLACE, EDINBURGH.

Two 1*s* tubes Calf No. 2. collected 8/1/02, sent out Jan. 17th, 1902, 8 P.M., from Edinburgh. Six days later the contents of the two tubes were added to sterile broth and the mixture was carefully divided into three, with one third of this mixture a gelatin plate was made. No colonies of any kind made their appearance. So far as extraneous organisms were concerned none had grown, even at the end of the tenth day On a similar plate prepared on agar 38 colonies made their appearance, eight of these were large discrete white colonies the rest were very tiny, both sets of organisms consisted of staphylococci, the first was staphylococcus albus the second grew more like a streptococcus, but on making a microscopical examination it was found that here again we had to deal with a staphylococcus. In the glucose formate agar some thousands of minute colonies and a few larger ones made their appearance in the depth of the medium, the smaller colonies consisted of very minute rods, the larger colonies of cocci. In the tube from another batch heated to 60° C for one hour not a single colony made its appearance, we may assume, therefore, that there were no spore-bearing organisms in this sample. Taking it altogether, this is a very satisfactory sample but it is somewhat difficult to understand the very large number of anaerobic organisms. It is evident that few of the organisms are derived from outside sources, they probably come rather from the skin of the animal, as only those that grow at a high temperature are met with.

GLYCERINATED CALF LYMPH, "PURE CULTURE BRAND," S. MAW, SON, AND SONS, 7–12, ALDERSGATE STREET, LONDON, E.C.

Three tubes at 1*s* This lymph was slightly opaque and granular and had a reddish tinge. It was sent out on Jan. 17th, 1902, and the tubes were plated on the 22nd. On the agar plate 30 colonies were developed, one of these being a typical staphylococcus pyogenes aureus, most of the others were staphylococcus pyogenes albus They were opalescent or white to the naked eye but a few of them had a yellow tinge, this, however, never became very marked A number of the other colonies had a lemon yellow tinge. On the gelatin three colonies, one of them liquefying, made their appearance, the slowly liquefying colony was made up of diplococci. In a third tube that was heated in agar for one hour at 60° C 210 colonies developed, so that in this case we had a fairly large number of spore-bearing organisms (1) of beaded rods and threads in which spores were not very distinctly marked, (2) smaller rods in which were well-marked spores, and (3) masses of thicker and shorter rods not developed into long threads In the glucose formate agar from 75 to 100 tiny colonies (strictly anaerobic organisms) developed in the depth of the medium. On the surface of this medium a large, white, soft colony, very like staphylococcus albus, made its appearance.

BIRMINGHAM CALF VACCINE ESTABLISHMENT, 204 VICTORIA ROAD, ASTON, BIRMINGHAM

JOHN ROUND, L.R.C.P., DIRECTOR.

Three very small green glass tubes, containing vaccine slightly opaque, granular and with a pink tinge, were obtained on two occasions The first sample left Birmingham on Jan 17th, 1902, and was plated out on the 23rd. The gelatin plate gave no growth of ordinary bacteria but five moulds developed on the surface It is possible however that this was an accidental contamination as the glass capsule covering the plate was accidentally displaced for a few seconds In glucose formate agar 50 or 60 anaerobic organisms developed There were also four surface colonies which gave an opaque moist, yeast like growth. A second sample was plated out on agar on Feb 13th 1902 vaccine source 'Fresh 5" (Jan 28th) In this plate 25 colonies developed, all of them staphylococcus pyogenes albus On the same day a sample was heated to 60 C for one hour From this sample not a single organism was developed.

DR. HIME'S CALF VACCINE INSTITUTION,

62, HORTON-ROAD, BRADFORD, YORKS.

Supplied to the Government in Ireland, the Egyptian Army, the Crown Colonies, boards of guardians, and public vaccinators.

This lymph was contained in a small phial. In order to obtain the lymph pure and to plate it out in known quantity the neck of the phial was carefully sterilised; the lymph was then withdrawn with a sterile capillary pipette (the phial being weighed both before and after it was emptied) and was transferred to a known quantity of sterile broth. The sample used was sent out on Jan. 17th, 1902, and was dealt with on the 22nd of the same month. In the agar plate 63 colonies made their appearance; these spread rapidly but there was no increase in number after the first four days. The colonies resemble those of staphylococcus pyogenes albus, both to the naked eye and microscopically. Rapidly-growing proteus-like colonies, very thin cloudy growths with a slight bluish or greenish tinge, and processes long and finger-like and thicker than the rest of the colony growing out from the margin consisted of short thick rods with the "battalion" arrangement; they contained no spores. From a gelatin plate made on the same date 120 colonies developed; eight of these liquefied the gelatin; of these colonies two were moulds and two had the crenated margins and finger-like processes described in the colonies appearing on the agar plate; most of the colonies, however, consisted of yeasts and long thick rods—many of them sporulating—and a peculiar mycelial growth which, however, had none of the naked-eye characters of any of the ordinary fungi. In the glucose formate agar tube from 100 to 120 minute colonies developed in the depth of the medium, but there was one surface colony, apparently an organism belonging to the potato bacillus group. A second set of tubes was inoculated from another phial. In an agar plate poured from one of these 55 colonies developed. In the agar tube heated to 60° C. for one hour five colonies were seen; these consisted of spore-bearing organisms—thin rods with swollen nodal points, a yellow sarciniform organism and leptothrix filaments breaking into long rods with square-cut ends; these long rods contained well-developed spores.

THE REBMAN PUBLISHING COMPANY,

129, SHAFTESBURY-AVENUE, CAMBRIDGE-CIRCUS, LONDON, W.C.

A sample of vaccine lymph was received from this firm on Jan. 18th, 1902. It was marked, "No. 641; 3 at 1*s.*; 17/1/02. Tubes if returned within 30 days from that date will be exchanged for fresh. Keep in a cool place." This lymph, contained in green-glass tubes, was plated out on the 22nd. On the agar plate 521 colonies developed: four of these colonies, with crenated edges, spreading rapidly, were made up of bacilli of two kinds—a thinner form very lightly stained and a thicker longer form which took on the stain deeply. The other colonies, also slightly crenated at the margins, were somewhat opaque, and at first sight had not the appearance of streptococci. On growing them in broth, however, it was found that a few streptococci were present; the bulk of the organisms were staphylococcus pyogenes albus. On the gelatin plates were 36 moulds; these developed regularly and were evidently not the result of accidental contamination of the plate. The glucose formate agar was crowded with some thousands of minute colonies. A second gelatin plate from No. 243 was made on Jan. 28th, 1902; from this 395 non-liquefying colonies and three moulds developed. Most of these colonies consisted of staphylococcus pyogenes albus. A sample of a second batch of vaccine lymph was heated for one hour at 60° C. and then plated out on agar; only two spore-bearing colonies made their appearance. These samples were more equal and the average purity was considerably higher than at the last examination of this lymph.

LYMPH FROM THE LOCAL GOVERNMENT BOARD LABORATORIES.

A tube of lymph for 25 vaccinations, supplied by the courtesy of Mr. Long, was received on Feb. 8th, 1902, cultivations being made and plates poured two days later. A quantity, 0·101 gramme, of this vaccine mixed with agar was found to contain 24 colonies when plated out; some of these were thick, white, opaque, and paint-like; they were very unequal in size but all consisted of torulæ. A peculiar iridescent colony was composed of staphylococci; the other colonies, thick, brownish-yellow in colour, with smooth margins, all consisted of staphylococci. The gelatin plate, made with half this quantity of vaccine, contained only two colonies, both of them staphylococci; one mould, evidently an accidental contamination, made its appearance at the extreme margin of the plate. In the glucose formate agar tube small aerobic colonies were found, one growing on the surface; there was also a large-lobed, somewhat cloudy growth in the depths—an anaerobic organism. The sample heated to 60° C. for one hour gave no growth of any kind.

TABLE XIII.—*Experiments with Lymph from the Local Government Board Laboratories.*

All the above vaccines have been examined on a former occasion and the results now obtained may be compared with the results recorded in THE LANCET of April 28th, 1900, p. 1227. Since this investigation was commenced we have had placed at our disposal three other samples of lymph of which a similar bacteriological examination has been made with the following results.

(14)

GLYCERINATED CALF LYMPH FROM MESSRS. BURGOYNE, BURBIDGES, AND CO.,

16, COLEMAN-STREET, LONDON, E.C.

This lymph, of which we were supplied with six small tubes at 2*s.* 6*d.*, was numbered 1359½ and was dated "14/1/02," with the note: "In the event of any complaint kindly refer to above number when writing." The lymph was slightly opaque and was very well mixed and homogeneous. The plates were made eight days after the lymph was dated;

the number of colonies was low. In the agar plate 49 colonies appeared; most of them consisted of staphylococci, some white, some with a slight yellow tinge; in all of these the margin was clean cut and the colony was moist and opaque-looking. In addition to these were greyish-yellow colonies somewhat similar in appearance to the above; they were, however, composed of short, curved, plump rods with rounded ends; these rods appeared to be rapidly dividing into still shorter oval bacteria. There were also some small club-shaped organisms which appeared to be involution forms, and in some of these the protoplasm was aggregated into small irregular masses, in which, however, there were no traces of spores. On the gelatin plate 10 colonies made their appearance; here, again, most of the colonies were staphylococci, some yellow, some white, but one very opaque colony was made up of yeast cells and a second which looked almost like a drop of paint consisted of thick rods. In the glucose formate agar culture were numerous very minute colonies which as they grew caused clearing up and "brightening" of the surrounding agar; they consisted of short plump rods with curved ends. It was difficult to count these colonies very accurately but they numbered from 400 to 500. In an agar plate made with vaccine that had been heated to 60° C. for one hour only three colonies made their appearance and these consisted of small rods in which spores ultimately developed.

MERCK'S PURE GLYCERINATED CALF VACCINE LYMPH.

PREPARED IN THE BACTERIOLOGICAL DEPARTMENT OF MERCK'S LABORATORIES, DARMSTADT.

LONDON OFFICE: 16, JEWRY, E.C.

Merck's lymph is prepared under strict aseptic precautions after the method used in the German Government Laboratories, and is not supplied unless it satisfies the following three conditions: 1. After slaughtering, the internal organs of the animal are examined by an official veterinary surgeon, it being imperative that those organs should be in a perfectly healthy condition. 2. The lymph is subjected to bacteriological examination (on glycerine agar plates), which is required to establish the absence of pathogenic bacteria. 3. The efficiency of the lymph is ascertained by test vaccination.

The following retail prices have been fixed for the tubes:—Small tubes for one or two inoculations, yellow wrapper, two for 1*s.*, six for 2*s.* 6*d.* Medium tubes for five inoculations, red wrapper, 1*s.* each; three for 2*s.* 6*d.* Large tubes for 10 inoculations, green wrapper, 2*s.* each, three for 5*s.* Tubes *should be kept in a cool place* and must be used up immediately after they have been opened.

Six tubes, No. 404, dated 8/2/02 (to be used before 22/2/02), for five inoculations. On examining these tubes they were found to be clear or slightly opalescent, with opaque areas. On pouring out this lymph into warm agar it was found to be finely granular. Cultivations were made on Feb. 11th, three days after the vaccine was dated. In the agar plate not a single organism made its appearance. In the gelatin plate two colonies had appeared at the end of nine days, one a yellow staphylococcus, the other a liquefying colony. In the glucose formate agar tube and in the specimen heated to 60° C. for one hour not a single colony developed during the period (over a month) that the specimens were kept under observation. This result was so good that it was thought advisable to test another sample. For this purpose a special sample that had been forwarded to THE LANCET Offices for examination—No. 415, dated 20/2/02 (to be used before 6/3/02)—was used for bacteriological investigation. Here again the results were excellent, only a single colony appearing in the agar plate, none on the gelatin plate.

ISTITUTO VACCINOGENO,

22, VIA ALTAGUARDIA, MILAN.

DIRECTOR: DR. GIUSEPPE SIGNORILE.

Passages quoted from letters from Dr. Signorile desired the Secretary of the Italian Chamber of Commerce in London to call our "attention to the pure vaccine lymph which the Government Institute under his administration already supplies to Switzerland and other countries. The lymph is sent in a new improved glass tube, having both extremities perfectly closed with molten glass, each tube being provided with a lancet, one side of which serves to file off when wanted for use the soldered point of the tube. The testimonials of many Italian and foreign municipal bodies and medical men have fully established the fact that the lymph, preserved by means of the new process adopted by the Milanese Institute, is absolutely pure and free from all pathogenic germs whatsoever." This sample was received on March 11th, 1902, but the box containing the vaccine was stamped "27/11/01." Plates were poured on March 15th with the following results. In the agar plates numerous colonies—at least 1500—were developed. This, however, is a low estimate rather than a count, as the organisms were so numerous that the colonies growing from them ran into one another. The anaerobic organisms were principally, if not entirely, staphylococcus albus. On the gelatin plate 280 colonies developed, 52 of these liquefying the gelatin. The opaque yellowish colonies that do not liquefy the gelatin are made up of groups of flagellated rods with rounded ends, the liquefying colonies resemble bacillus subtilis very closely. In the glucose formate agar shake tube a large number of colonies developed anaerobically and much gas with a very evil smell was formed. The contents of a tube placed in agar and heated to 60° C. for one hour contained 172 organisms that had resisted this temperature, so that not only was the number of ordinary organisms very high—from which, owing to the length of time which had elapsed since the material was prepared, we must gather that the glycerination (?) has been very imperfectly carried out—but the number of spore-bearing organisms is very much higher than is met with in most of the other samples that came under our observation. These spore-bearing organisms are mostly thin rods, but in some of the opaque colonies with crenated margins a peculiar "sulphur" fluorescent organism, made up of shuttle-shaped rods and rods with rounded ends, is present. This lymph was not used as a vaccine on the human subject.

FORMATION OF VESICLES.

Although doubt has been thrown on the possibility of determining whether a vaccine lymph is sufficiently potent or not by any experiments except those on the calf, the monkey, or the human subject, it has now for some time been recognised that under certain conditions experiments on rabbits may afford evidence on this point, and experiments with many of these lymphs were carried out to determine whether they all acted equally powerfully on rabbits; for, as pointed out by Calmette, if the lymph is active for rabbits it is probably still more active in the case of the human subject. There can, we think, be little doubt that here we have a valuable method at our disposal; for, comparing the results obtained with the human subject, it was found that in every case the comparative results were the same, but in most cases the vaccine effects produced in the latter were very much more marked than were those produced in the former. In Table XVII. the activity of the vaccine is indicated by the number of asterisks inserted opposite to the different lymphs. In a few cases in which very marked reactions were obtained in the human subject the results in rabbits were not so marked, but in almost every case where this happened there was evidence of mixed infection, the vaccinal result being far from typical. Bearing this in mind the relative activity of any sample of lymph may be indicated by taking the sums of the numbers of asterisks in the two columns under "rabbit" and "human." High bacteriological purity associated with great vaccinal activity must be taken as the essential features of a good vaccine lymph, and bearing these features in mind it is unnecessary to lay down any hard-and-fast line as to which is the best and most trustworthy lymph in the series. Each vaccinator should, in the first instance, select those lymphs that seem to conform to these requirements and promise the best results and then, amongst these, having found one with which he is satisfied, keep to it.

In drawing up Table XVII. the total number of organisms has not always been taken as the exact measure of the bacteriological purity of a sample of vaccine lymph. The aerobic organisms growing on agar at the temperature of the body have been looked upon as giving the most trustworthy indication as to the successful glycerination of the lymph. Next in importance appear to come those organisms growing on gelatin, and then come the spore-bearing organisms. The anaerobic organisms—unless actually pathogenic or in very large numbers—appear to be of comparatively little importance except in those cases where gas, especially foul-smelling gas, was formed; and the reason that one of the lymphs has been placed in a very low position is that very large quantities of such foul-smelling gas were developed in the medium when the cultivation was maintained at the temperature of the body. It is scarcely necessary to insist more strongly upon this point.

* In No. 4 the spore-bearing organisms are comparatively numerous and in Nos. 5 and 6 the anaerobic organisms are out of all proportion to the numbers of other organisms present.

The weight of the vaccine used was obtained as follows. The glass tube or phial with its contents was first carefully weighed, then immediately after withdrawing the lymph the glass with the small quantity of vaccine remaining was again weighed. Before driving out the vaccine the tubes were carefully washed with an antiseptic solution and were allowed to dry in a sterile box. One of the sealed ends was then snipped off with sterile scissors and the closed end was gently warmed near a small gas flame in order to cause expansion of the air within the tube. The lymph driven out by the expanded air was received directly into sterile broth, agar, or gelatin, as the case might be, and never came in contact with anything but the cut end of the vaccine tube until it reached the inside of the sterile test tube. It has, of course, been pointed out that these vaccines vary considerably as to the degree of dilution and that the number of bacteria contained is not altogether a measure of the purity of the lymph before glycerination. It must be insisted, however, that whatever be the dilution of the lymph the number of organisms applied to the abraded surface is that contained in the definite volume of lymph used for vaccination and that if a lymph is sufficiently active to produce well-marked vesicles and distinct constitutional effects and at the same time contains a small number of extraneous organisms, such lymph is the best for the purpose for which it is designed to be used, and the best stage of glycerination and degree of dilution are those where the number of extraneous organisms is small, the number of vaccine organisms still being sufficiently large to bring about the desired results. It is for this reason that in coming to a decision as to the quality of a lymph not only the number of organisms present should always be taken into consideration but also the actual activity of the vaccine.

In compiling these figures access has been obtained to records of over 400 vaccinations. It is interesting to note that there is scarcely a doubt that all the vaccine lymphs at present on the market are, as regards their capability of producing vaccine vesicles, of very trustworthy character at some period or other after their preparation. It will be noted, however, that the series examined affords examples of three sets of conditions. (1) Those in which the glycerination is well carried out and the number of organisms present is small but the vaccine virus still remains sufficiently potent to induce typical vaccine vesicles without giving rise to a too violent reaction. If, when using such lymphs, proper precautions are taken to sterilise the skin and to prevent the access of extraneous germs to the abraded surface, the vaccine reactions, both local and general, run a typical course and the patient is very little inconvenienced except for a period of two or three days when the vaccine fever is at its height. This forms a kind of intermediate series, for we find that (2) there are certain lymphs in which are numerous extraneous organisms It appears from examination of these organisms that certain manufacturers are careful to avoid glycerinating the lymph to such a degree that all organisms are got rid of, indeed some of them claim that the presence of certain cocci *is of distinct advantage in so far as such organisms* assist in the production of the local lesions. There can be no doubt that in vaccines prepared on this plan most active local lesions are obtained, but especially in stout people, the accompanying œdema is often very marked and the patient may suffer considerably from constitutional disturbance—fever, malaise, &c. This is notably the case when the vaccine virus itself apart from outside organisms, is potent. Chaumier's, Rohman's, and several of the other lymphs in which the number of organisms is comparatively high (see Table XVII) may be taken as types of this lymph (3) At the other extreme are certain lymphs in which the *glycerination and dilution* appear to have been carried to such a point that there is only a slight margin between what may be called first-class vaccine lymph and lymph that though perfectly pure is not absolutely trustworthy As a type of this class Merck's is perhaps the best. It is practically free from all extraneous organisms and certain batches gave by far the best results as regards vaccination that were obtained In the cases on which these observations were made the typical pearly vesiculation, the depressed centre of the vesicle and the narrow areola were all exceedingly well marked The fever was typical though coming on at a comparatively late period Other samples of this same lymph gave exactly the same typical vesicles when the lymph did 'take,' but the number of successful insertions was comparatively small, whilst in the case of a third series of samples with which inoculations were made within a couple of days after they were received from the agents in London not a single successful insertion was obtained in six cases (18 points) though in other patients inoculated on the same day and in exactly the same fashion with some of the lymphs less highly glycerinated every insertion was successful.

On a careful comparison of those various lymphs with those examined on former occasions we are of opinion that there has been (1) a very marked improvement in the quality of the vaccine lymphs supplied during the last few years, (2) that glycerination of lymph if precautions be taken to secure a lymph 'clean' in the first instance may be carried out without interfering in any very great degree with the activity of the vaccine virus, (3) that the presence of a large number of organisms in an active vaccine lymph renders the local lesion more severe and modifies alters or renders more severe the constitutional symptoms, causing both local and constitutional symptoms to make their appearance at an earlier period than when well glycerinated vaccine is used, (4) that the œdema, though fairly severe in certain cases where well glycerinated calf lymph is used is far more severe and much more obstinate in those cases in which imperfect glycerination allows of the persistence of a large number of extraneous organisms, and (5) that although prolonged glycerination especially when the vaccine is very dilute, appears to render the lymph less trustworthy, the vesicles when produced by this lymph are so typical and the course of the process is so definite that it is worth running the risk of having to vaccinate a second time in order to obtain such satisfactory results. Where any doubt at all remains in the mind of the practitioner we would recommend that over glycerinated rather than under glycerinated lymph should be obtained A careful study of Table XVIII will enable those interested to determine for themselves which of the lymphs are probably most suitable for their purposes.

CAUSES OF "BAD VACCINATION

We are strongly of opinion that many of the bad results obtained in vaccination are due to the presence of one or other of the following conditions imperfect sterilisation of the skin and want of protection against the invasion of the weakened and abraded tissues by extraneous organisms. We have found that, given a good lymph the application of a plentiful supply of soap and water a razor to take off hairs and surface epithelium ether to remove fatty and sebaceous matter alcohol to wash away the ether, superficial vaccination and protection of the vaccinated surface throughout the whole course of the local manifestation of vaccinia, most excellent results may be obtained. The best means of protecting the local lesion is the application of several folds of sterile lint containing no chemical disinfectant, this is held in position by strips of adhesive plaster, a layer of boric lint may then be placed outside this dressing and the whole may be changed as soon as the slightest evidence of moistening by serum appears in the boric lint. One of the *most certain methods of producing severe* œdema is for the patient to use his arm freely and to bring about perspiration just before and after the vesicles have begun to form Rest free action of the bowels and the above precautions are the best preventives not only of vaccinal œdema but also of secondary sloughings We are more firmly convinced than ever—to quote from our previous report—that the 'freer the lymph is from extraneous pyogenic and other organisms the less marked will be those inflammatory concomitants which are so familiar to all vaccinators' and that "much of the irritation that has often been regarded as essential" to a successful vaccination 'is not so much due to the action of the vaccinal organism itself as to organisms acting as irritants upon the cutaneous tissues. We are informed that the best results are invariably obtained with those lymphs which produce late vesiculation and that if a lymph be free from bacteria, especially streptococci and staphylococci, and if typical vesicles slow of development with little inflammatory areolæ and late in coming to maturity be obtained the patient is properly vaccinated In the first report we had not obtained sufficient information on these points to be able to give a definite opinion but with the information now placed at our disposal we have no hesitation in speaking most definitely on this point

EXPERIMENTS WITH OLD LYMPHS

Lymphs which had been kept since the beginning of the year 1900 were plated out on agar in order to see how far they differed bacteriologically from the same lymphs examined at that time.

TABLE XVIII.—*Giving Results of Plating Out Lymphs that had been Kept (Cool and in the Dark) for a Couple of Years*

Lymph	Plated out	Number of colonies on agar
Local Government Board 6/2/00 Series 370	27/2/02	Only six tiny colonies
Establishment for Vaccination with Calf Lymph 20/ /00		Seven colonies
Ferris and Co 1900		
Helman 20/3/00		One colony
Institut de Vaccine Animale calf 73, 14/3/00		One colony
Maw Son and Sons 1900	„	About 120 mostly spore bearers
Dr Ilimo's Calf Vaccine Institution 20/ /00		154; amongst these is the yellowish green colony found in the 190 samples

Further, in order to determine whether vaccines which in the fresh condition undoubtedly give results on rabbits, remain potent for any length of time three rabbits were inoculated with old lymphs—the first three of the above (Local Government Board Renner's and Ferris's). In every case the results were absolutely negative

---

THE EDUCATION OF THE DEAF AND DUMB.—On May 30th Earl Egerton of Tatton presided at the Westminster Palace Hotel over a conference composed of the representatives of the governing bodies of schools for the deaf and dumb The chairman stated that the report of the Royal Commission on the success of the oral system, especially in Germany and Italy had led to a large increase of the teaching of that system, while the standard of the teacher had been raised. The conference passed resolutions to the effect that institutions for the deaf should be exempt from rates and taxes, that the obligatory condition in the Blind and Deaf Act 1893 of raising one-third of the expense of maintenance from private sources should be removed, that an increased grant ought to be allowed, and that the reduction of the grant when a child was absent from the schoolroom through illness although remaining in the institution should not take place

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THURSDAY, MAY 29TH.

THE sittings of the summer session of the General Council of Medical Education and Registration were resumed to-day in the Council's hall at 299, Oxford-street, W., Sir WILLIAM TURNER, the President, being in the chair.

The Case of Dr. Tyndale Watson.

The Council considered the case of Dr. William Tyndale Watson of Tottenham, Middlesex, N., registered as Mem. R. Coll. Surg. Eng. 1861, M.D. Univ. Dubl. 1867, but stated to possess the further unregistered qualifications of M.D. Oxon., Dip. State Med. Dubl., who had been summoned to appear before the Council on conviction for misdemeanour, he having in November last pleaded guilty to a charge of indecent assault brought against him in the Central Criminal Court and been sentenced therefor to a month's imprisonment.

Dr. WATSON appeared and stated that Mr. A. A. Strong, solicitor, would represent him before the Council.

Mr. WINTERBOTHAM (solicitor to the Council) explained the charge and Mr. STRONG proceeded with the evidence in mitigation of punishment.

Mr. JOSEPH HOWARD, M.P. for the Tottenham Division of Middlesex, was first called and in answer to Mr. STRONG said that he had known Dr. Watson for rather more than 40 years. He had always held a very high opinion of him. Witness had met him occasionally and the doctor had frequently been at his house as a friend. He had attended witness professionally but none of his family. Witness had always found Dr. Watson to be of irreproachable character.

Dr. GILBART SMITH testified that he knew Dr. Watson well. He had known him very intimately for more than 30 years and had found him most highly honourable and absolutely opposed to such a thing as he had confessed to have done. Witness had the highest respect for him. About 10 years ago he had attended him when he was suffering from the effects of influenza. He saw him with another medical man. They thought to recommend Dr. Watson to take a sea voyage but they had not made a recommendation in that direction because of the state of the doctor's mind, which might have made his presence on board ship dangerous. There had been signs of insanity in his family, a brother having had to be put under control.

In answer to Sir CHRISTOPHER NIXON witness said that he and the other medical man were afraid to permit Dr. Watson to take a sea voyage because they thought he might commit suicide.

Dr. G. VIVIAN POORE stated that he had known Dr. Watson for about 20 years and had always the highest opinion of his character. He certainly never thought him capable of such an action as in court he pleaded guilty to.

The Rev. CHARLES HOWELL, vicar of Trinity Church, Tottenham, said that he had known Dr. Watson for about 30 years and from the first had had a high opinion of his personal character. He had constantly met him and he should say that the general opinion of the people of Tottenham was what his own was.

Mr. E. WOOD, Enfield, a registered medical practitioner, who stated that he had known Dr. Watson for about 27 years, said that he had always had the highest opinion of him. He was surprised that Dr. Watson had been charged with anything of the sort he had admitted. Witness had a letter from the North Tottenham Medical Society testifying to the high esteem in which he was held among the practitioners of Tottenham.

Mr. DOUGLAS WATSON, M.R.C.S. Eng., L.R.C.P. Lond., in practice in Essex, and a son of Dr. Watson, informed the Council that during the illness which occurred 10 years ago his brother and himself had had a great deal of trouble in looking after their father. On several occasions they had to see that he was not permitted to take chloroform or any opiate. After his brother's death three years ago his father broke down again and witness had the same trouble and anxiety as previously he had had.

Mr. STRONG, in answer to a question as to whether Dr. Watson would go into the witness-box, said that the doctor was in a bad condition of health, but he was ready to present himself if the Council wished to ask him any questions. He explained that Dr. Watson had been in prison for a month, the Recorder having postponed sentence from the one session at which he pleaded guilty to the following session, and on being brought up again the sentence imposed released him from custody on the day on which it was given.

Dr. GILBART SMITH volunteered the statement that while Dr. Watson was in prison he saw him on two or three occasions. He was in hospital then and he thought that the certificate of the prison doctor had had something to do in influencing the Recorder's judgment in the case.

Mr. STRONG, in addressing the Council, made an appeal for merciful consideration of the doctor's case. Dr. Watson, he said, was born in Ireland 63 years ago. He had been in Tottenham since shortly after obtaining his degree of Doctor of Medicine in 1867 and he had acted as medical officer of health of Tottenham and officer at the Tottenham Dispensary. Subsequently he had received from Dublin an honorary Diploma in Public Health. When he resumed work after his trouble of 10 years ago his practice increased and he took his eldest son into partnership with him. That son died three years ago and Dr. Watson, in addition to the mental anxiety caused by his death, had to bear the anxiety of finding under the copartnery contract a large sum of money for his son's young widow. He, moreover, had the practice thrown on his own hands and unfortunately he had tried to get strength to carry it on efficiently by taking such drugs as morphia; he suffered from constipation, nervous depression, piles, and enlargement of the prostate gland; they must all feel that there must have been some strong mental or physical reason which had caused him to slip from the path of virtue. Dr. Watson, however, had never attempted to deny his fault. He admitted that he had sinned but would not add to it by telling a lie. He had undergone imprisonment but that was absolutely nothing to the punishment he had suffered in other ways. On his release he found his practice practically gone and had to part with it for a mere song; he found his friends deserting him, his money was exhausted, and he at once left off practice and went to Swanage where he hoped to remain for the rest of his days, having ceased to have all practical connexion with that profession which he loved so much. If the Council struck him off the Register he would feel that to be the greatest blow of all. If there was a case in which mercy should be shown it was this, and for the sake of the doctor's wife, to whom he had been married for 35 years, and for his sons and daughters, and because of the many years during which he had gone quietly on his way without committing fault, he, Mr. Strong, entreated them to show Dr. Watson mercy.

The Council deliberated on the case *in camerâ*. On the readmission of strangers, the PRESIDENT, addressing Dr. Watson, said: The Council has carefully deliberated on your case and this is what I am instructed to say, "That having heard evidence bearing on the state of your mental and physical health the Council does not see fit to remove your name from the Medical Register."

The Case of Dr. Robert Rendall.

Consideration was next given to the case against Robert Rendall, of 19, St. Peter's-road, Great Yarmouth, registered as M.B., Mast. Surg. 1893, Univ. Edin. Dr. Rendall appeared for himself and Dr. A. G. Bateman as representing the Medical Defence Union.

Mr. WINTERBOTHAM explained the position in which this case stood. He said that the charge against Dr. Rendall was brought before the Council last November and was this—

> That you have been guilty of infamous conduct in a professional respect, particulars of which are that you have accepted and continue to hold the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practises canvassing for the purpose of procuring patients, and that you have approved or acquiesced in such canvassing.

Having deliberated on the case the Council came to the conclusion "that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council. The Council feel it their duty to express their sense of the gravity of the facts which have been proved against you; but in order to give you an opportunity seriously to reconsider your position in relation to the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company, Limited, they have adjourned the further consideration of the charge until the next session, when you will have to appear and satisfy the Council as to your conduct in the interval."

Due notice to attend had been served on Dr. Rendall and the following letter was received from him on May 13th :—

19, St. Peter's-road, Great Yarmouth, May 13th, 1902.

DEAR SIR,—I beg to lay before the General Medical Council the following statement—viz. : that I sent in my resignation as medical officer to the National Medical Aid Co. and as medical referee to the Liverpool Victoria Legal Friendly Society on Dec. 24th, 1901, and my connexion with them has been entirely and completely severed since Lady Day, March 25th last.

I inclose the acknowledgment of my resignation sent me on Jan. 3rd, 1902, by the secretary of the National Medical Aid Co.

Under these circumstances will you kindly let me know if it is necessary for me to attend on the 29th inst. ?

Yours obediently,
R. RENDALL.

W. H. Winterbotham, Esq.,
Solicitor to the General Medical Council.

[INCLOSURE.]

The National Medical Aid Co., Ltd.,
Registered Offices, 80 & 80A, Fleet-street,
London, E.C., January 3, 1902.

DEAR SIR,—I beg to acknowledge receipt of your letter of the 24th ult., which was read to the directors at their last meeting, and I beg to inform you that your resignation as medical officer of the company at Great Yarmouth contained therein has been accepted and will come into effect on March 24th next.

By order of the Board,
E. T. HARWOOD, Secretary.

Dr. R. RENDALL, 19, St. Peter's-road, Great Yarmouth.

He (Mr. WINTERBOTHAM) had informed Dr. Rendall that it was necessary he should attend the meeting of the Council and he was present.

The PRESIDENT, addressing Dr. Rendall : Have you any further evidence to offer?

Dr. RENDALL : No, sir.

The PRESIDENT : Do you wish to address the Council on the matter?

Dr. RENDALL : No, sir, I have nothing further to say; just to affirm the fact that I resigned the appointment I held in the Medical Aid Company and I have no intention of having in the future any connexion with it.

Dr. BATEMAN informed the Council that he had nothing to say.

The Council then sat in private for some minutes. On resuming in public the PRESIDENT, addressing Dr. Rendall, said : I am instructed to communicate to you the decision at which the Council has arrived—namely : "That having considered the facts and evidence submitted by you in relation to your action since the last session the Council has resolved to proceed no further in regard to the charge proved against you."

An Application for Registration.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, it was agreed to adopt a recommendation of the English Branch Councils that they should consent to the registration of Mr. Abiathar Wall, Lic. Soc. Apoth. Lond., 1871, Lic. R. Coll. Phys. Edin., 1872, Mem. R. Coll. Surg. Eng., 1872, a medical practitioner entitled to be registered under the Medical Act (1858), but who neglected to effect such registration until after the "appointed day" (June 30th, 1887), under the Medical Act (1886).

The Case of Dr. William Park.

The next business on the order paper was consideration of the case of William Park, registered as of Gartlea House, Airdrie, M.B., Mast. Surg., 1897, Univ. Glasg., who had been summoned to appear before the Council on a charge of unprofessional conduct. Application was made to have the hearing postponed till November on the ground that Dr. Park was abroad, that the ship in which he had taken up the position of "ship's doctor" would not return to this country before July next, and that he wished to be heard in his own defence; but on the advice of Mr. MUIR MACKENZIE (the Council's legal adviser) it was resolved to proceed and for upwards of an hour the hearing of, and deliberation on, the case went on *in camerâ*. On the readmission of the public

The PRESIDENT said : The Council have deliberated on this case and their judgment is "that William Park has been guilty of infamous conduct in a professional respect and they do direct the Registrar to erase his name from the Medical Register."

The Council adjourned.

FRIDAY, MAY 30th.

The Council resumed work to-day, Sir WILLIAM TURNER presiding.

Appointment of Committees.

The Pharmacopœia, Finance, Dental, and Students' Registration Committees were reappointed without change. In the Examination Committee Dr. Windle was appointed in place of Dr. Glover and Dr. Finlay in place of Dr. Pettigrew. In the Education Committee Dr. Reid's place was given to Dr. Mackay, while in the Public Health Committee the place resigned by Dr. Pye-Smith was given to Mr. Jackson. In the case of the Dental Education and Examination Committee Dr. Finlay was appointed in place of Dr. Reid, and Dr. Bennett was made an additional Irish representative.

The Finances of the Council. Scheme of Reform.

The next business was the consideration of the report of the Financial Relations Committee appointed in June, 1901, "to consider what amendments, if any, to the Medical Acts are necessary in order that the relations between the Council and the Branch Councils may be readjusted and how the financial position of the Council may be placed on a satisfactory basis." In their report the committee said that the following points had become clear :—

(*a*) That the financial position of the Council and its branches is unsatisfactory and calls for consideration and decided action on the part of the Council.

(*b*) That the deficit, on the Council's income and expenditure account, on the average of the last seven years' amounts to full £1200 per annum.

(*c*) That this state of the Council's affairs is due to the special constitution, the small income, and the work of the Council and Branch Councils, as determined by the Medical Acts, 1858-1886, and it cannot be met by such economies as are proposed in the reports of the Finance and Special Finance Committees referred to in the narrative.

(*d*) That to readjust permanently the relations between the Council and the Branch Councils it will be necessary to obtain certain amendments of the Medical Acts, 1858-1886.

It will render the situation of the Council plainer to first submit the general conclusion arrived at by Mr. Tomes from an examination of the original state of the finance of the General Council and the effect thereupon of the 42 years which have elapsed since the initiatory payments of registration fees began in 1858.

During the first few years after the institution of the Register large sums were received in the form of £2 registration fees paid by those entitled to admission to the Register, and these payments, in diminishing amounts continued over a good many subsequent years. An investigation of the accounts shows that there was received from such £2 registration fees £35,000 in round numbers.

The interest actually received upon such part of this sum as was not devoted to current expenditure but was invested has, during the whole period since the Council was instituted, amounted to £40,485 in round numbers, so that the initial receipts and the interest received amount together to £75,485. In addition a sum of about £2600 has been derived from profit upon the issues of the Pharmacopœia.

But the present assets do not materially exceed £41,600, so that the whole of the Pharmacopœia profits, the current registration fees, and, in addition, some £34,000 derived from interest, have been expended.

From this it follows that throughout the whole period of the Council's work the current £5 registration fees have failed to meet the expenditure by something like £900 a year, although it is possible that there may be individual years or even periods when the above-mentioned fees were adequate, if the receipts were large and the expenditure happened to be small.

This aspect of the matter, the insufficiency of the £5 registration fees to pay their way unaided, even over the whole period which embraces many favourable years, is of vital importance to a full recognition of the fact that the present deficiency of resources is inherent in the limitations contained in the Medical Act, 1858.

It ought in this connexion to be remembered that the Act in question was, by reason of the circumstances surrounding its inception, tentative, and it is not surprising, therefore, to find that after an experience of over 40 years some of its provisions have proved to be inadequate.

It will now be readily understood that the Council is at present dependent on the surplusage of fees remaining as accumulations of the income of the English and Scottish Branch Councils and that these assets are rapidly diminishing, since the work of the Council causes at the present time an annual deficit of over £1200. The Irish asset of this kind has already been exhausted.

The assets of the General Council consist in brief of the Pharmacopœia, of the difference between the actual value of the freehold premises and the amount for which they are mortgaged to the English branch, and of the present value of the sinking fund. The assets of the English branch consist of the mortgage on the present premises of the Council which stood in the last balance-sheet at £25,764 and of an investment—i.e., £9149 in Consols (taken at 90). The assets of the Scottish branch consist of £4770 in Consols (taken at 90). There is thus, taking the investments together, a sum of about £13,919 in the form of liquid assets available at any moment.

In addition to such available assets the Council possesses house property (i.e., No. 299, Oxford-street, and No. 16, Hanover-square) which represents in actual cost £25,764, and which probably stands for a considerably larger sum if the asset be realised.

The foregoing represents the whole resources of the Council. As regards its financial stability, it is clear that in the year 1901 the deficit was £1509; at this rate, and that of the annual deficit shown in Mr. Frere's report for the preceding three years, all the liquid assets will be exhausted in eight or nine years and it will then become necessary to commence to realise the value of the premises.

Since, therefore, the efficient work of the Council will cease from lack of resources within the forthcoming decade a complete scheme of financial reform must be adopted at the earliest possible date and from what has been already said it is obvious that such a scheme requires fresh legislation for its execution.

SCHEME OF READJUSTMENT OF THE FINANCIAL RELATIONS OF THE COUNCIL AND BRANCH COUNCILS AND OF REFORM OF THE FINANCES OF THE COUNCIL.

Any scheme of financial reform must fulfil the following conditions:—

1. Provision of sufficient revenue for the execution of the duties of the Council.

2. Provision of a central administration for the income and expenditure of the Council and Branch Councils.

The details of such a scheme consequently may be most conveniently considered under the heading of (1) Revenue, (2) Administration.

(1) REVENUE.

The revenue of the General Council is at present provided under Sections XIII. and XV. of the Medical Act, 1858, which enact that the bulk of the income—viz., fees paid for registration—is to be paid to the branch councils, and that the Council is to obtain its chief supplies by requiring contributions from the Branch Councils by a percentage-rate on all moneys received—i.e., in effect at a rate proportionate to the registrations effected at each Council's office.

The income of the Branch Councils is derived from only two sources—viz., the fees for registration and the interest on the accumulation, if any, of income—i.e., original registration fees—before referred to.

The latter amounts in the case of the English Branch Council to about one-third, of the Scottish Branch Council to about one-twentieth of the first-named source. The Irish Branch Council now has only the registration fees as its source of income which has to be supplemented by an annual grant from the funds of the General Council.

Hence the reliable revenue is the amount of the annual registration fees, plus the rent of the Hanover-square property—viz., £250 per annum, less income tax. The amount of the annual registration fees varies, and in the year 1901 only amounted to £7060, whereas the restricted expenditure of the Council for the same year amounted to £10,065.

The essential source of the Council's revenue being thus inadequate it is essential that a revision of the system of registration fees be instituted, as it is needless to take into consideration the only remaining alternative of assistance from the Imperial Treasury.

The system of registration fees at the present time includes an initial registration fee of £5 and small fees for subsequent additional registrations, but there is no fee charged for the entries on the Students' Register.

There are three courses of revision possible if a larger revenue is to be secured: to raise the initial registration fee for practitioners, to substitute a small annual registration fee for an initial payment, or to institute a student's registration fee.

Objections can be readily raised against each of these propositions, but at this point only one primary consideration can be discussed—namely, how far would the instituting a registration fee for students or the raising of the initial registration fee for practitioners or the payment of an annual registration fee reasonably satisfy the requirement of an adequate revenue.

Undoubtedly an annual fee from each registered medical practitioner would provide a large revenue, but the committee are of opinion that the provision of an addition to the annual revenue can at present be best created by adopting the institution of a students' registration fee and by raising the fee for the initial registration of practitioners. The committee estimate that if the latter fee be raised from £5 to £7 and if a fee of £1 be charged for a student's registration, the resultant addition to the Council's revenue per annum will amount to somewhat over £4000. Such an increase of the resources of the Council would at least save it from the bankruptcy with which in a few years' time it will be threatened if action is not soon taken to place the accounts on a stable basis.

(2) ADMINISTRATION.

The present system of administration of the funds of the Council and Branch Councils is very cumbersome and unbusinesslike.

It has, in fact, led to the embarrassment and insolvency of the Irish Branch Council.

To effect the necessary reforms in this particular all that is needful is to reverse the present system and to provide that all moneys paid into the offices of the Branch Councils shall be forwarded forthwith to the General Council and that all accumulations of income by the Branch Councils shall be transferred to the account of the General Council.

It would further be necessary to provide that all needful expenditure, either on behalf of the General Council or the Branch Councils, should be defrayed by the General Council.

Such financial reforms would in no wise interfere with the registration rights of the Branch Councils.

To carry out a scheme of this nature amendment of the Medical Acts would be necessary.

The report then set out in detail the requisite alterations in the Medical Acts. The recommendations of the committee were as follows:—

1. That the principles of amendment of the financial position of the Council embodied in the report of the Financial Relations Committee be approved.

2. That the Financial Relations Committee be reappointed, with instructions to draft, with the assistance of the legal advisers of the Council, a Medical Acts Amendment Bill, carrying out the principles of financial reform approved by the Council.

3. That such draft Bill be considered at the next session of the Council.

NOTE BY MR. HORSLEY.

The foregoing report is the report of the committee as a whole.

I desire to record my belief that a complete solution of the financial difficulties of the Council is only to be secured by the institution of an annual registration fee and by extensive reform of the Medical Acts.

VICTOR HORSLEY.

NOTE BY DR. HERON WATSON

Supplementary to the Report of the "Special Committee" of the General Medical Council appointed to consider "the financial relations of the Council."

In circumstances such as those which present themselves to the General Medical Council, where, in the matter of finance, a deficit either exists or is imminent, the great general principle should not be lost sight of, as equally applicable to an individual or a public body—viz., to curtail expenditure to such a point as shall prevent matters becoming more embarrassed—and then, when an assured solvency has been reached, to determine if the expenditure in the past, whether in whole or in detail, was either necessary or beneficial, and then conclude whether it is to be continued or how it may be best met.

1. Such a line of action upon the part of the "Special Committee" appointed by the General Medical Council to consider the financial relations of the Council and to suggest some measure of relief seems to me to be hardly met by the proposal that the initial registration fee for practitioners should be raised or that an additional charge should be imposed upon the somewhat slender income of the great mass of practitioners whose names appear upon the Medical Register, as such a measure will most certainly risk the opposition of the medical profession and would tend to render the General Medical Council unpopular.

2. A self-imposed restriction upon the faculty of much speaking on the members of the Council, with a commensurate shortening of the meetings, a greater number of hours devoted to the actual business of the Council and its committees, implying, if need be, morning, afternoon, and evening sittings, might well be adopted as a preliminary tentative measure, and should this increase in the number of hours prove insufficient the withdrawal of all fees for attendance upon the meetings while only travelling and hotel expenses be continued might most reasonably be adopted.

Certainly it appears to me that some such self-denying regulation should be passed so as to manifest to the medical profession that what is done by the Council is due to a single-minded determination to confer benefits and not to bind burdens upon the profession at large.

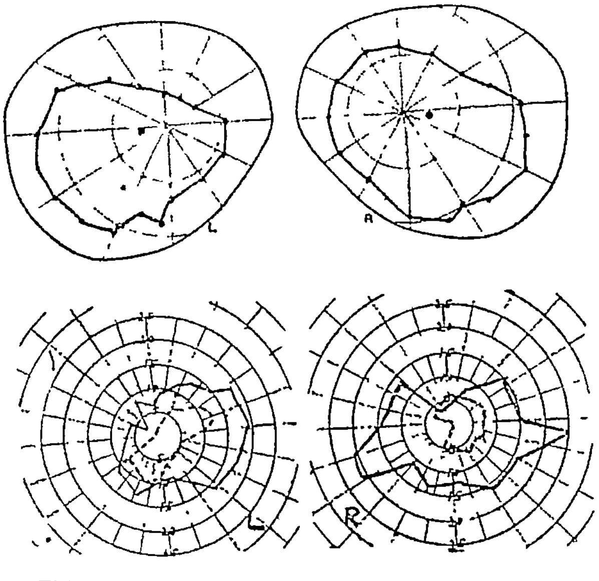
3. So far as I have considered this matter—and it is no new question to me—I am strongly impressed with the feeling that any further pecuniary burdens imposed by this Council for the performance of its duties upon the medical profession will be regarded as a grievance likely to be resisted at every point, more especially where this additional impost can only be obtained by the introduction in Parliament of an amendment to the Medical Acts.

4. In such circumstances it may be well carefully to consider whether before such a tribunal as the Houses of Parliament the medical practitioner upon the Register on the one hand or the General Medical Council on the other be the more likely to obtain support such as will be required to meet successfully the exigencies of such a conflict.

PATRICK HERON WATSON.

The PRESIDENT explained that he himself was chairman of the committee but he thought that it would be well that Mr. Horsley should present the report.

Mr. HORSLEY moved that the report be received and entered on the minutes. He felt a certain difficulty, he said, in the matter. He had appended to the report a note simply to preserve his political consistency on this question. He had always held, and still held, that an annual registration fee was the proper means of their meeting their financial difficulties, but in the committee when the vote was taken on this point he found himself in a minority of one. With this explanation he ventured to ask the Council to accept the report as a step forward in financial reform. He believed that as a matter of fact the Council was prepared to consider fully any project which could be made to it which had a reasonable hope of success, but in saying that he would direct the attention of the Council to another note at the end of the report, a most important note by Dr. Heron Watson, because in that note there was raised a question which really was scarcely before the committee. The committee had a distinct reference to it to find out how in their opinion the finances of the Council might be renovated and Dr. Heron Watson thought that a more fundamental step should be taken in the direction of diminution of expenditure. He believed that the members of the committee were not satisfied that the present deficit would be met in this manner and they certainly were not satisfied that however reasonable it might be in an individual to cut down expenditure in the manner suggested it would be reasonable for this Council to take the step considering the work it was expected to do under the Acts of Parliament. The committee had come to the conclusion that, roughly speaking, from £10,000 to £12,000 were required to balance the accounts of the Council, and, further, they were assured that if there was a small increase in the initial registration fee of practitioners and if a registration fee for students was created these two means would provide the necessary funds. As to the mode in which the expenditure and income of the Council should be conducted the committee proposed to introduce a very sweeping system of reform. The present position of the Council was most anomalous—a position thrust upon it by the Medical Act of 1858. Although it had to conduct really the whole business that was ever brought before the Council or its branches it nevertheless actually had no reliable income above a few hundred pounds. The income only approached it indirectly through the branches. This system the report asked the Council to abolish altogether. The Council was asked to provide that the income as it was paid into the branch offices should be at once sent to the central office of the General Council, so that that would centralise another instance of inaccurate terminology, because the evidence of heredity is not so common as is the affection of collaterals, of brothers and sisters. This "family" feature is clear proof of the congenital nature of the tendency to vital failure which the disease manifests. It is really ataxic paraplegia depending upon slow changes in the posterior and lateral columns but associated with other symptoms in speech, &c. In this malady the abiotic tendency is clearly congenital. Males suffer more frequently than do females, but not in the same degree as in some other analogous maladies.



Fields of vision. The upper for white, the lower the central region for red (continuous line) and green (broken line).

Friedreich's disease was the first of the kind to be distinguished and is the best known, but the attention which has been given to it has revealed the wide variation in the precise characters presented by cases which cannot well be separated from typical forms. The characteristic weakness, the weakness and unsteadiness of the legs, sometimes ataxy of the arms, the change in speech and nystagmus, are often found to be associated with some impairment of sensation, and with either loss or with excess of the knee-jerk; the condition of speech also is found to vary and there may or may not be mental alteration. The cases pass by degrees into another group which has been thought to be distinct. In this the most conspicuous feature is the swaying disturbance of equilibrium when standing, with or without evident weakness of the legs; there may be loss or excess of the knee-jerk but there is seldom any disturbance of cutaneous sensibility. The arms may present any form of incoördination or none. Speech is commonly altered, slow and monotonous, sometimes with confluent articulation, sometimes with a staccato utterance. There is almost always nystagmus and mental change is more often marked than in Friedreich's disease. The difference in other symptoms is generally one of degree only and depends on the age at which symptoms come on. This is chiefly during the second half of actual childhood. Resemblance of the symptoms to those of disease of the cerebellum has caused the malady to be called by the inexact and clumsy name "heredo-cerebellar ataxy." Although heredity has been found in a few cases merely a family association has been commonly met with. Disease in the lateral columns has been found but changes are greatest in the posterior columns and the direct cerebellar tract, which seem to convey afferent impulses to the cerebellum; their defect deranges its coördination of impulses to guide the cerebral motor centres. Affections of these upbearing fibres, conveying impressions from the muscles, seem thus to cause this peculiar "cerebellar" ataxy, as distinguished from the pure incoördination of the legs met with when the inbearing fibres to the cord degenerate, as in ordinary tabes. All the facts regarding the disease show that it is a true abiotrophy, a degeneration of certain neurons from defect of vital power, but the precise distribution of the defect varies in different cases. Probably many of the neurons in the brain which connect different parts and associate and harmonise their functions also waste, and thus the mental change may be explained. But the special pathology of this affection is beyond my present subject.

Before I leave this group of abiotrophies, those of earli life, it may be well to point out that not all the morbi states which seem congenital are really such. Caution especially needful in the case of the diplegias which da from birth, because they are so frequently due to meninge hæmorrhage during a tedious or instrumental labour. T narrow pelvis which causes this in one child may have t same effect on another and thus we may have the semblan of a family affection by that which is purely acquired. T birth damage tends to improve as time goes on, abiotroph tend to increase, but when slight in degree they may see sometimes to become stationary. The varying course o served in both muscular and nerve affections makes probable that the degree and extent of the deficient vit endurance may vary much in different cases with cor sponding variations in the extent and character of t symptoms that it causes.

The second group of degenerations are those which occ at the other end of life. While general life still seems f of vigour the nutrition of some neurons fails; they slow die. The neurons which most frequently thus decay a the spinal motor neurons—those which sometimes fail, we have seen, at the very beginning of life. According the position of the tracts which suffer first and most t effect is the symptoms of spinal progressive muscular atrop or of labio-glossal paralysis. These are more frequent late life than isolated degeneration of the upper, cerebr motor neuron which causes spastic paralysis, although t does sometimes suffer alone and almost always together wi the lower neuron in the ordinary atrophic cases. The maladies often come on without any apparent cause simp because the term of life for those structures is reached a they decay in a true abiotrophy. When any exciti cause can be traced it is usually one which is alo inadequate—some general depressing influence, such anxiety or grief, which must act equally on all the oth structures and tissues, reducing the vital energy of all. B vitality only fails in those which have inherently a le degree; their defect is sufficient to make the reduction these, though the same as in the others, relatively great sufficient to end their life. Without this influence th might or might not have persisted to the end of general li The apparent cause does not lessen the significance of t facts which show these affections to be essentially sen abiotrophy.

Mental change, especially simple mental failure, also oft occurs under the same conditions and no doubt from a sl degeneration of cerebral neurons which connect and combi others in a way we cannot yet perceive. Another sen malady, paralysis agitans, must be referred to vital fail in some cerebral motor structure. It is a striking example its conditions and course of a cerebral abiotrophy. In sp of its obvious seat in motor structures, in spite of its strong progressive character, it seems never to entail the decay the motor neurons which connect the brain, the spinal co and the muscles. It formerly seemed to me like a degene tion peculiar in kind, such as we are reminded of by th which causes the hair to become white from lack of pigme though growth is still luxuriant and presents a contrast wi the degeneration which causes baldness. But the rece discoveries compel us to look to the extremities of t branching processes of the motor cells, the dendrites wh pass into the spongy grey substance, for the source of t motor impulses which the fibres conduct that pass throu the nerve-cells without interruption. A change in th nutrition may disorder function yet leave the vital cell a the nutrition of the neuron as a whole unaffected. It is al conceivable that there may be a change in the relation the dendrite endings to those which stimulate them a induce the motor impulses. We know too little to be ab to form an adequate hypothesis. But paralysis agita generally occurs without any adequate cause and must regarded as a pure effect of a special defect in vitality—as form of abiosis. Its occasional occurrence, even in extre form, in middle life, also without discernible cause, is co sistent with this view, for the same is true of other sen maladies.

A third group remains, a large and important class degenerations the precise nature of which we cann discern. They are the varied degenerations that occ the aggregation of the income. Naturally they must have the expenditure similarly controlled from the centre and that also was proposed in the report. There was an annex to this part of the subject to which he must refer at greater length. Members who had given particular attention to the difficulties of the financial position of the Irish Branch would remember that the sums of money standing to the credit of the English and Scotch Branches had always been a source of mystery and it was only three years ago that they learned that the branches had no legal right to hold those accumulations of income. The report proposed that the money should be handed over to the account of the General Council. He hoped and believed that this proposal would recommend itself to the Council and there would be no particular difficulty in carrying it out The alteration of the income was, of course, a difficult procedure, for it would require an amendment of the Medical Acts.

Mr Jackson seconded the motion for the reception of the report and its entry on the minutes.

Dr Bruce intimated that he desired to add his name to the note prepared by Dr Heron Watson

Dr. Atthill said that he concurred in everything in the note except one point and that was that he did not think it would be wise to discontinue the payment to members of the Council.

The motion was then agreed to.

Mr Horsley, by way of raising a general debate, moved the first recommendation of the committee—

> That the principles of amendment of the financial position of the Council embodied in the report of the Financial Relations Committee be approved.

Sir Christopher Nixon formally seconded this motion.

Dr Norman Moore said that he would like an answer to the question whether the Council had power under the present Acts to compel students to register If it had not this power then this proposed fee would be an uncertain source of revenue. Obviously it would be necessary to obtain a clause in an Act of Parliament compelling the registration of students.

Dr. Atthill That is the intention.

Dr Norman Moore said that this was what he wanted to learn. If students were to be compelled to register there must be some advantage either to the students or to the public or to both. Were the Council prepared to demonstrate that? What would be the advantage to the students? None What would be the advantage to the public? It would not secure that the students had studied any longer time. He was afraid that the House of Commons would be very particular to inquire what were the advantages. It seemed to him that in relying upon this as a source of revenue they were relying upon what it was improbable they would get, and he would go further and say at once that he thought it would be a most unjustifiable thing to turn a voluntary registration, whatever its benefits, into a means of increasing the income of the Council. How did the public look upon that sort of procedure? A man said, 'I am doing something I do it for nothing but it is a very good thing to be done and now I want some payment for doing it." As to the question of charging a larger fee to practitioners on registration, he regarded the keeping of the Register as the most important function of the Council and the one in which it did the most useful service to the public The Council was clearly entitled to charge a fee when a man's name was placed on the Register Would it be possible to charge a higher fee? His own opinion was that if the fee were bigger there would be no difficulty in obtaining it but before they went to Parliament for this power they must make it clear that they used the funds now in their possession in the most thrifty fashion and that by this additional income they would do still better work. He could not help feeling that it would lead to very elaborate criticism of the way in which they spent their time and it would be said, "Is it worth while to buy more of this kind of thing?" He thought that that was the way the public would put it.

Dr Atthill said that it would be absurd to attach a fee to registration which was not compulsory He thought it should be compulsory and that such an arrangement would be for the advantage of the public and the profession

Dr McVail said that he did not think they should discuss this question of the registration of students. Parliament would never sanction registration merely as a means of getting a fee for this Council He was confident, however that Parliament would sanction a raising of the fee for practitioners on entering the Register if the Council made out a sufficiently good case. What would the case be? He dissociated himself from the view taken by Dr Norman Moore. Dr Norman Moore's speech implied that the Council did its work in such a way that Parliament would not buy any more of it. He did not know whether this Council was more perfect than other bodies but it was not less perfect. Its volume of minutes was a proof of the quality of its work and he would not have the slightest hesitation in going to Parliament so far as the quality of the work of the Council was concerned. He did not know any body which wasted less time. By the Act of 1858 the Council consisted of 23 members and these 23 were to elect a twenty fourth who should be President. The Council now consisted of 31 members, the other seven members having been imposed upon it by Parliament. The Act specified that members of Council were to be paid fees and the Act imposed upon the Council the printing and issuing of these registers. The difference between 24 members and 31 would practically account for the financial position in which the Council now found itself Moreover, the Government had frequently asked the Council to do work not connected with the Act of Parliament. They had sent down the Midwives Bill for instance, and asked the opinion of the Council with regard to it, and days had been spent discussing matters at the instance of the Privy Council. These were reasons why the Government should not be unwilling to increase the revenue of the Council. Again, the Act of 1858 gave the Council the power of visiting examinations but did not compel the Council to visit examinations. The Act of 1886, however, compelled the Council to inspect the final examinations. That was a new work put upon the Council and he never could understand why the Council did not demand an increase of funds in that connexion. He submitted, therefore, that they had a strong case for going to the Government and to Parliament for additional assistance. While that was so he objected to putting a tax upon the medical student who, in his opinion, was quite enough taxed already It was a different matter when a man was going in for registration on the Medical Register Of all the methods suggested in this report undoubtedly the increase of the registration fee was by far the simplest and the one that would commend itself to the Government. The fee was already in existence and it was only an increase that was proposed He did not think there would be any difficulty in getting the Government to assist them if they went about the matter in the right way

Sir Christopher Nixon said he wished to express his regret that at a time when the Council had so many critics one of its own members should speak adversely of its work and do so unsupported by any grounds whatever For himself he did not know a body which did its work as well as this Council or had a higher object in view The work of this Council must be maintained both in the interest of the public and of the profession, and if it was to be maintained there must be sufficient funds for the purpose. Dr Norman Moore said that he did not see any great use of the register of medical students but the Council attached great importance to it, and he wished to say that by seeking to have a compulsory registration of medical students they went a long way towards securing a uniformity of curriculum. That was shown in the contention which had arisen between the Royal Colleges in England and the Council and if they had a compulsory registration there would be no difficulty He had had a conversation with an influential Member of Parliament whose view was that there would be no difficulty in getting a moderate increase in the registration fee, and the amount this member suggested was £10. In the case of a barrister he had to pay £50 Stamp Duty before he was called to the bar If members of this Council considered that they did their duty honestly and faithfully to the public, to the State, and to the profession, he thought there would be no difficulty in securing a sufficient sum of money to carry out their work efficiently and he for one most strongly objected to the suggestion that members should receive no fee for their attendance. He did not think they were called upon to make this additonal sacrifice

Sir John Batty Tuke said that a compulsory registration of students would infer the right of this Council to lay down conditions of registration, and although that was a consummation he longed for he thought that no one who knew the condition of feeling amongst the various bodies could fail to recognise the amount of opposition it would raise. Indeed, he thought the possibilities of obtaining the compulsory registration of students were extremely remote. Very soon after he came to this Council he saw that the Council was gradually slipping into monetary difficulties, that the income would in a comparatively short time fall short of the expenditure, and he and the late Dr. Leishman had the question very fully discussed on at least two occasions and endeavoured in every way they could to get the Council to think of the serious state of affairs which was likely to ensue. The remedy which appeared to him then as the only one likely to be of any effect was a reduction of the fees of members and he still held to that. He thought that the Council would be in a much more dignified position if members rendered their services to the profession and the public without any remuneration whatever. A further suggestion he made at the time was that the Council if it objected to the reduction of fees should sit for a greater number of hours each day. What would be the state of the case if they went to Parliament? They would show that a large proportion of the expenditure of the Council consisted of fees paid to members, and the first question asked would be, "How long do you work?" The answer was that they worked four hours a day. Rightly or wrongly the average Member of Parliament would say, "We work eight, nine, and 10 hours a day." It would be perfectly useless to lay down to Parliament the difficulty and the nature of the work of this Council. The first thing Parliament would say was, "You must not ask the profession to make further sacrifices; try to make some sacrifices yourselves;" and he believed that it was upon these lines they should work. He was entirely in accord with the opinion expressed by Dr. Heron Watson.

Sir **Christopher Nixon**: Would it not be quite competent for any member not to take the fee?

Dr. **Heron Watson**: Yes; and he would be regarded as a most superior person.

Dr. **Bruce** was sure that all Dr. Norman Moore meant to say was that when they went to Parliament they would be asked, Were they already doing work sufficient for the money they got? He agreed with Dr. Watson and Sir John Batty Tuke that they should seriously consider in what way they could economise the money they already got. For instance, he thought the meetings of each session should not be confined to one week, the committees meeting on the Saturday before the Monday on which they started.

Mr. **Brown** considered that economies might be effected in various directions. For one thing, he thought the work and expenditure of the Scottish Branch Council ought to be done centrally by the Council itself and that would effect a considerable saving, for it appeared to him that the expenditure of the Scottish Branch Council was somewhat extravagant, if not excessive Then they might reduce the number of members of the General Medical Council and the representation of licensing bodies who were merged into one. He could not see why the Royal Colleges of Physicians of London and Surgeons of England, which formed the English Conjoint Board, should be represented by two members.

Dr. **Norman Moore**: It is not a fact that the Royal College of Physicians of London is merged into the Royal College of Surgeons of England.

Mr. **Brown**: Practically they are—in the English Conjoint Board.

The **President** suggested that Mr. Brown was going beyond the report.

Mr. **Brown**: Well, sir, if we determine to go to Parliament for economical measures I shall bring before the Council economies in the directions I have indicated. I do not feel quite sure that sufficient grounds have been made out for putting a registration fee on students, but I certainly think that we might increase the initial fee for the registration of practitioners, and I think it would conduce to the greater correctness of the annual issue of the Medical Register if there was a small annual fee, for even with all the care that is now taken in the preparation of the work there are in it many errors which would not be visible if we had annual registration.

The **President**, after a pause, remarked that they had now got to consider how they were to come to a conclusion on the matters which the report raised. Mr. Horsley's motion was before them proposing to approve of the principles of amendment of the financial position of the Council as embodied in the report. The question of revenue had been discussed but the very important question of administration had not been touched. The question of revenue resolved itself into three parts—the raising of the fee, substituting an annual fee for an initial fee, and instituting a students' registration fee. He should hold that the principles of amendment would embody one or other of these three parts. If they agreed to proceed with amendment they might take a vote as regards these three parts and then they would raise a direct issue. The question was how to bring the subject before the Council so as to get its opinion and he thought that he should have to ask Dr. Heron Watson to formulate an amendment to Mr. Horsley's motion.

Dr. **MacAlister** suggested that in deciding upon the principles it might be advisable to express these one by one in the form following:—

> That the Council approves in principle of the following proposals for fresh legislation contained in the report of the Financial Relations Committee:—
>
> 1. That a fee of £1 be charged for registration in the Students' Registers.
> 2. That the initial registration fee for practitioners be raised from £5 to £7.
> 3. That the financial administration of the funds should be remodelled so far as the mutual relations of the Council and its Branch Councils are concerned.

Mr. **Horsley** accepted this expansion of his motion but he considered that Mr. Jackson's notice of motion in respect to annual registration should be dealt with as a separate and substantive proposal after (1) had been disposed of, because it was an expression of opinion.

The **President**: Then you might say a few words on the question of administration.

Mr. **Horsley** thereupon read that part of the report headed "(2) Administration," and beginning with the words, "The present system of the administration of the funds." He thought it might well be in the minds of a given Branch Council that the reform advocated was of such a drastic nature that it would encroach on the authority and rights of the Branch Councils. It did not do that at all. The influence and rights of the Branch Council remained unimpaired. If the scheme did anything it did this—it permitted Branch Councils to spend money and send in the bill to the General Council to pay. Of course, if there was dissatisfaction with the conduct of any Branch Council there would be an opportunity of discussing it in the General Council. So far as the Irish Branch Council was concerned, its present position was entirely due to the structure of the Medical Act of 1858, the system of assessment authorised by that Act being wholly insufficient for the proper conduct of the branch which certainly should be reconstituted.

As no one seemed desirous to say anything further on the question of administration the **President** asked if anyone had any remark to make on the question of the transference of the monies of the Branch Councils to the General Council.

Sir **John Batty Tuke**: Transference involves an Act of Parliament.

The **President**: Of course.

Dr. **Bruce** thought there could be no objection.

Dr. **McVail**: Should not this be sent to the branches?

The **President**: It was sent two or three years ago.

Dr. **McVail**: I do not think the question of their giving up what was entrusted to them by the Medical Act was. This is too big a question to be settled right off by the Council. It should be first sent to the branches.

Dr. **Payne** was of the same opinion.

Dr. **Little** thought that surely that would be an unnecessarily cumbrous mode of procedure. The Council could vote on the spot.

Dr. **Atthill's** objection to further reference to the Branch Councils was that it would be simply waste of time.

The **President** proceeded to ask the Council to decide on the first part of Dr. MacAlister's expansion of Mr. Horsley's motion.

Dr. **Heron Watson** proposed as an amendment:—

> That before the Council commits itself, to the principle that further legislation is necessary for the continued solvency of the Council the Financial Relations Committee be requested to report on the economies which it may be possible to effect in the expenditure of the Council and its branches in the direction of the abandonment of fees, and an increase in the time expended on the work of the Council and of its committees in each day of session.

Dr. **Bruce** seconded this amendment.

The **President** pointed out that the distinction between the motion and the amendment was that they should endeavour to bring into harmony with each other the income and expenditure by further legislation, or economies should be brought about internally without fresh legislation.

Dr McVail thought this amendment should be split into two parts. It proposed the abandonment of fees and the increase of work. These two subjects should be taken separately. He was altogether unfavourable to any increase in the Council's hours of work, because, with reading the official papers issued in the morning, attending meetings of committee, and afterwards the meeting of Council, the hours already were as long as they ought to be. So far as fees were concerned he was prepared to support Dr. Heron Watson's proposal.

Dr. Bennett was opposed to the idea of putting aside the question of fresh legislation. In his view it was perfectly absurd to talk of the Irish Branch Council going on with the present mode of assessment. The branch was, and must continue to be, in a state of bankruptcy so long as that mode of assessment lasted.

Sir William Thomson said that they ought to hear this amendment explained before they further proceeded with it.

Dr Heron Watson If members read the committee's report and my note appended to it they should fairly understand the position

On a division 11 voted for the amendment and 14 against it, five did not vote and one member was absent

Dr Norman Moore proposed an amendment with the same preliminary words as Dr Heron Watson's contained but concluding with the words "expenditure of the Council and its branches in general relation to the fees and the work of the Council."

Dr Bruce seconded this amendment, the terms of it *in extenso* being :—

> That before the Council commits itself to the principle that further legislation is necessary for the continued solvency of the Council the Financial Relations Committee be requested to report on the economies which it may be possible to effect in the expenditure of the Council and its branches in general relation to the fees and work of the Council.

Mr Horsley submitted that that was precisely what the Special Financial Committee reported on 18 months ago—a period prior to that at which Dr Norman Moore became a member of the General Council.

On a division only eight members supported the proposal and it was accordingly declared to have been lost.

On the question that the preamble and (1) be adopted Mr Horsley expressed the thought that it would be better if he withdrew from the position of proposer, seeing that he wished to second Mr Jackson's proposal for an annual registration fee. The Council consented to permit this and accepted the motion as being proposed by Dr Atthill and seconded by Sir Christopher Nixon

Dr. MacAlister It is clear that it is proposed to put students' registration in the Bill contemplated, if agreed to it would appear for the first time in an Act of Parliament.

Dr. Windle For the first time the registration of medical students would become compulsory

The President Yes.

Dr Norman Moore Then I think that the proposal should begin with the words, "That students' registration should be compulsory and that," &c.

Mr Horsley said that the committee had not raised the great question of the compulsory registration of students All that they asked to do was to establish a registration fee and the question of compulsory registration ought not to have been brought up at this moment. It would really not come upon the table until the proposed draft Bill was there. He submitted that all the Council was asked to do now was to agree to the desirability of instituting a students' fee.

Dr Windle said that surely the question of compulsory registration was wrapt up in the proposal to institute a fee and he did not see how they could vote on the subject unless it was made clear that compulsory registration of students was included. Otherwise they would be voting for a source of income on which it would be impossible to rely, because it would be perfectly open for any licensing body to say that it did not require students' registration, and if several of the licensing bodies adopted the same course the income from this source would of course be very uncertain.

Sir Christopher Nixon The fee for registration depends altogether on the compulsory registration.

Dr McVail I entirely approve of compulsory registration of students in itself as a principle, but I entirely object to bring it into operation simply as a means of taxing students for furnishing this General Council with funds. The Council ought to get its funds solely from practitioners entering the profession.

Dr Atthill The fee paid by a student before registration would stand exactly on the same ground as registration for a practitioner for both must be paid by the parents.

Dr Little I think the debates in this Council have shown that unless we can register students at the time they begin their work we cut away the foundation from medical education. I do not think there is a better way of increasing the Council's funds than by imposing a fee on students for registration.

Mr Horsley If this debate is continued someone must move an amendment. No mention is made in the report of registration as a subject.

Mr Brown said he was anxious to vote for the institution of some fee for the registration of students and that meant compulsory registration, for it was obvious that if registration was to be optional no student would come and put down a sovereign merely for the sake of having his name inserted in the Students' Register

The Council divided, with the result that 13 voted for, 12 against, three did not vote, and the other three were absent.

It was accordingly carried by a majority of one

> That the Council approves in principle of the following proposals for fresh legislation contained in the report of the Financial Relations Committee: (1) that a fee of £1 be charged for registration in the Students Register

Dr Atthill, seconded by Sir Christopher Nixon, then moved

> (2) That the initial registration fee for practitioners be raised from £5 to £7

Mr Jackson proposed the following as an amendment —

> That in the opinion of this Council it is desirable that an annual licensing fee of 10s be substituted for the present registration fee of £5; the annual fee not to be paid for 10 years after registration by those who have already paid the £5 registration fee.

In supporting this proposal he said it appeared to him that the work of the Council had very much increased since its institution At the present moment it looked to him that if the public wanted to convert the Council into a court for the punishment of medical men for lapses from the path of virtue, as the proceedings during this session indicated that they were somewhat inclined to do so, it was quite certain that their work would further increase. Various modes might be suggested by which the work might be reduced but if they were to carry on efficiently they must have a largely increased income. He need hardly say that they had new universities springing up all over the country and representation of these must entail a certain amount of extra expenditure on the Council's part. His strong belief was that in the circumstances the best way to obtain an increased income was by the proposal he now made for an annual licence. If they had annual licences on the basis he proposed that would give them an income of £12,000 a year It would be said that there would be great difficulty in the collection of the annual payment, but surely their collection could be done in the same way as the subscription of men all over the world to the British Medical Association was obtained. There was no doubt that annual registration would secure greater accuracy in the yearly issue of the Medical Register He had spoken to many medical men in the country and they had approved of the alteration he now suggested He thought the change would not be objected to by medical men generally, especially when they were convinced of the benefits that would arise from it. Of course, the Council would have to go to Parliament to obtain the powers to alter the system, but he did not see why they should not.

Mr Horsley seconded the amendment. He said that the subject had been discussed by the committee and he knew perfectly well that several of them were absolutely opposed to the proposal. At the same time he wished to point out that if the General Medical Council were going to Parliament for fresh legislation Parliament would ask a *quid pro quo* for any advantages that might be demanded for the profession, and he thought this would be a perfectly justifiable thing to ask from the profession—an annual bargain as between the public and the profession. An annual registration fee was, he thought, a thing that would cause Government to look with great favour on any amendments of the Medical Acts which the General Medical Council might propose.

Sir Christopher Nixon was strongly opposed to an annual assessment. It would impose something on the profession for which nothing was given in return. Parliament was very unlikely to give it, even if the Council had the machinery for collecting an annual tax. The profession would acquiesce in the increase of the registration fee, but as they would have to pay it themselves they would be strongly opposed to an annual tax and would doubtless take such steps as would ensure the rejection of the proposal by Parliament.

Dr. **HERON WATSON** declared that the scheme was unworkable. If any such were adopted it would be an act of policing and it would certainly degrade the Council in the eyes of their professional brethren.

Sir **WILLIAM THOMSON** said that he was once of opinion that the principle of this proposal was one which would meet the difficulty of the Council's approaching bankruptcy, but he had come to the conclusion, after considering the matter very carefully, that the suggestion to put an annual fee on the profession was not one that would be palatable. There was no use of citing the collecting power of the British Medical Association, for the case of that Association and that of the General Medical Council were entirely different. If a member of the British Medical Association was late in paying his subscription he did not cease to be a member of the body, but it was an entirely different thing when they came to deal with a payment for keeping a man's name on the Register. Their medical practitioners were scattered all over the country and if they did not pay at once how was the payment to be recovered? The difficulties were so many that he should not like to encourage departure from the existing system—payment at entrance to the profession. If the initial fee was to be raised he did not think there should be any cheese-paring in the matter and they might as well say 10 guineas instead of the £7 which was now named. Ten guineas was a light fee for entrance to a profession. He was sure there would be no objection to it from the general body of the profession and the gentlemen who would have to contribute that sum would be only too glad to pay it.

Dr. **BRUCE** said that the difficulty of collecting rendered the scheme absolutely out of question, but there was also this to face—if they were to charge every member of the profession an annual tax the profession must have absolutely entire direct representation. The scheme was not a workable one and put forward the worst way in which an increase of funds might be secured.

Dr. **ATTHILL** was quite willing that the registration fee should be 10 guineas.

Dr. **MACALISTER** opposed the amendment. He said that if it were carried the profession would have to be remodeled.

After a few remarks in reply from Mr. **JACKSON** the amendment was rejected by 22 votes to 3. Three members did not vote and three were absent.

Sir **WILLIAM THOMSON** moved as an amendment—

> That the registration fee be raised from £5 to a sum not exceeding £10.

Dr. **ATTHILL** seconded, and the proposal was carried by 18 votes to 7, and on being put as a substantive motion was adopted by 18 votes to 6.

On the motion of Mr. **HORSLEY**, seconded by Sir **CHRISTOPHER NIXON**, it was agreed without discussion—

> (3) That the financial administration of the funds should be remodeled as far as the mutual relations of the Council and its Branch Councils are concerned.

Mr. **HORSLEY** next moved the second recommendation of the committee, namely:—

> That the Financial Relations Committee be reappointed, with instructions to draft, with the assistance of the legal advisers of the Council, a Medical Acts Amendment Bill, carrying out the principles of financial reform approved by the Council.

The wording of that recommendation, he said, was in general terms, because it was thought the Council might alter the principles embodied in the report. In order to give effect to it, it was necessary that they should have a draft Bill constructed. In that Bill certain important questions would be included as being necessary for the fulfilment of the report.

The **PRESIDENT**: Do you propose to go beyond the report in the framing of the Bill? Do you mean that the Bill should cover any ground other than the ground specified in the report and in the principles of it?

Mr. **HORSLEY**: Oh, no. The committee will act according to the instructions of this Council.

The **PRESIDENT**: Oh, no; only in terms of this motion.

Mr. **HORSLEY**: This motion will become the instructions of the Council to the committee.

The **PRESIDENT**: What I wanted to make quite clear was that the committee who were to draft the Bill were to be restricted to principles embodied in this report. It might be argued that there is not much use in bringing forward a Bill when there is not much chance of its being passed, but it seems to me that if this Council would put on its minutes such a Bill it would be a step in the direction of securing what it wants.

Sir **CHRISTOPHER NIXON** seconded the motion.

Dr. **MCVAIL** said it seemed to him that this proposal would seriously affect the Scottish Branch Council, which had been a very active body in past times and which he wished to see active again. To what extent it would be effective he did not quite see, and therefore what he should do would be to retain his right to act against the motion if, on investigation, he found that it would destroy the powers which were inherent in the Scottish Branch. As he understood the position at present, that branch would loose all power and would become simply a local committee of the General Council.

Dr. **NORMAN MOORE** suggested that owing to the great difference of opinion which had been evidenced in the divisions it would better the Council's position in the country if they waited until something like unanimity was secured before they drafted a Bill that they would like Parliament to pass.

Dr. **ATTHILL** hoped they would have unanimity, but how could they come to agreement if they had not the heads of the measure before them? Once these were in sight let them modify them as much as they liked, but in his view it would be a great mistake to postpone this matter indefinitely.

The **PRESIDENT**: As to what this suggested Bill is to cover, in my judgment it cannot cover anything beyond what is stated in the report—that is to say, an alteration of sections of the existing Acts and the provision of new sections limited to three things.

Dr. **MCVAIL**: Would you specify what you mean? We have done nothing in respect to administration.

Mr. **HORSLEY** suggested that by the adoption of Dr. MacAlister's expansion of the committee's recommendation the position had certainly been somewhat altered.

Dr. **MCVAIL**: This question is growing as we go on. It is a bigger question than I thought it was when we started the discussion and if it in its result is practically to annihilate the Scottish Branch Council it is a question that cannot be settled before the Scottish universities and the Scottish medical corporations have had an opportunity of discussing it.

The **PRESIDENT**: The committee will have to approve of the financial reform approved by the Council. We have agreed to the three sections as suggested by Dr. MacAlister and the committee's recommendation now before the Council covers these and nothing more.

Dr. **MCVAIL**: I shall vote against this.

Dr. **MACALISTER** thought a slight modification of the recommendation would get rid of any difficulty. He suggested the addition of the words "and embodied in the suggested amendments to the Medical Acts on pages 13 to 17 of the report of the Financial Relations Committee."

This addition was consented to and the complete motion now was:—

> That the Financial Relations Committee be reappointed, with instructions to draft, with the assistance of the legal advisers of the Council, a Medical Acts Amendment Bill carrying out the principles of financial reform approved by the Council and embodied in the "suggested amendments to the Medical Acts" on pp. 13–17 of the report of the Financial Relations Committee.

The **PRESIDENT** asked if this should be voted on at once.

Several members informed him that it was now after six o'clock, the fixed hour for adjournment, and they were not prepared to sit later.

The **PRESIDENT** thought they might in the circumstances suspend the Standing Orders.

Several members: Too late.

The Council adjourned.

SATURDAY, MAY 31ST.

The Council met again to-day with Sir **WILLIAM TURNER** in the chair.

The Finances of the Council.

Discussion was resumed on the following motion, moved by Mr. **HORSLEY** and seconded by Sir **CHRISTOPHER NIXON**, viz.:—

> That the Financial Relations Committee be reappointed, with instructions to draft, with the assistance of the legal advisers of the

Council, a Medical Acts Amendment Bill, carrying out the principles of financial reform approved by the Council and embodied in the "suggested amendments to the Medical Acts" on pp. 13–17 of the report of the Financial Relations Committee.

Dr. Little moved an amendment to adjourn the discussion and empower the President to make such provisional arrangements for the next meeting and generally for carrying on the business of the Council in the interval as might appear to him most conducive to economy.

Dr. Bruce seconded this amendment.

The President said that while the amendment was in order it was a question whether he should undertake for even a short period the position of an amiable despot.

After a short debate the amendment was rejected.

Sir John Batty Tuke, continuing the debate on Mr Horsley's motion, said that if it were passed it would indefinitely postpone the question of fiscal reform. A Bill would be drafted and it would come before the Council and it would lead to a series of academic debates, and supposing a Bill were approved by the Council it would go to Parliament where it would rank as a private Member's measure and might remain for years and years before being passed Another consideration was whether there was anything behind this motion. Had they any assurance that this Bill when it went before Parliament would remain the Bill of this Council? Had they any assurance that it would not be indefinitely extended? It seemed to him very much as if it were a lever for the upsetting of the whole of the existing Medical Acts. If the Council wanted to save money it must begin from within. All talk about Bills and things of that kind represented so much wasted time. Either go on spending the money—the £20,000 or £30,000—as long as it lasted and then go into bankruptcy or let them institute practical economy and exercise some sacrifice.

Dr Mackay said that when the Bill had been drafted it would be for the Council to consider it carefully and in the meantime he thought it would be well for the Council to consider what economies could be practised. He therefore moved as an addition to the motion "and that it also be remitted to the committee to consider what economies in the expenditure of the Council it may be possible to effect."

Dr. Finlay seconded this proposal.

Dr Pye-Smith said that while he agreed with the endeavour to simplify the finances by having them in one place, he did not agree with the justice of increasing the registration fee of professional brethren which he thought would be very unfair indeed. In his opinion one reform they should aim at was a reduction in the membership of the Council.

It was agreed to accept the addition to the motion proposed by Dr Mackay.

Mr. Horsley assured the Council that the committee was perfectly ready to see what economies could be practised.

Dr Atthill, seconded by Mr Tomes, moved the closure and it was agreed to without a vote.

A vote was then taken on Mr. Horsley's motion with the addition proposed by Dr Mackay, when 20 members voted for it, four against it, six did not vote, and one was absent. The motion was accordingly carried.

On the motion of Mr. Horsley, seconded by Sir Christopher Nixon, it was agreed that the report of the committee should be presented at the November session.

Report of the Finance Committee.

The next business was the consideration of the report of the Finance Committee for the year 1901. The following passages occur in it:—

The Finance Committee report that the income of the General and Branch Councils for the year ending December 31st, 1901, was £8557 0s 7d.; the expenditure for the same period was £10 065 12s 7d.; consequently there is a deficit on the year's working of £1508 12s.

From Table A it will be seen that the receipts from fees show a decrease of £79 4s., the English Branch having received £8 7s. 6d. less than in the previous year, the Irish Branch £105 16s. less, and the Scottish Branch £32 18s 6d. more. A further falling-off in the general amount received from these fees must be anticipated in the near future, for the number of students registered in the last three periods of six years (which is the average time taken to complete the curriculum) is as follows:—

Years.	Students	Average per annum.	Decrease in average.
1884-1889	11,631	1,938	—
1890-1895	11,178	1,863	75
1896-1901	9,575	1,596	267

That is to say, that the average number of students registered in the last period of six years is 267 per annum less than the number registered in the previous similar period and the effect must appear before very long in the receipts from fees.

A statement of the expenditure of the General Council comparative with former years will be found in Table B. The chief items calling for explanation are:—

(a) A decrease of £439 19s. in fees to the General Council, the sessions having been three days shorter than in 1900.

(b) A decrease of £164 10s in various committee fees, the cost of extraordinary meetings having been exceptionally high in 1900

(c) An increase of £47 16s. 3d in the printing of Registers, to which the attention of the Stationery Office has been called, and a reduction is expected this year

(d) An increase of £55 19s 9d. in house expenses, being the cost of the electric fan in the Council chamber

(e) A decrease of £263 17s 2d. in law expenses.

(f) An increase of £315 13s 10d. for inspection of examinations, a new cycle having been begun.

(g) An increase of £57 17s 7d. in miscellaneous expenses, caused by the fee paid to Mr Frere for his report on finance.

The summary of the results is as follows: the income of the General and Branch Councils in 1901 was £100 8s. less and the expenditure £370 12s. 11d. more than in 1900.

A new table, C, shows comparatively the income and the expenditure of the three Branch Councils for the past three years and it will be noted that the expenditure is increased in each case by the exceptional expenses of the election of the Direct Representatives. The chief points which call for attention are (1) that the increase in office expenses of the English Branch is mainly due to the issue of circulars of inquiry regarding the accuracy of addresses in the Register; and (2) that the fees paid to the Scottish Branch Council show an increase because the meetings summoned in connexion with the election are not charged to that account, as is done in the case of the other two branches.

Table D shows that the Pharmacopœia being excluded, the expenditure of the General and Branch Councils for 1901 has exceeded the income by £1508 12s., as against the average excess for the past seven years of £1201 19s. 1d The percentage-rate is 93·51, as against the average for the same period of 91·80. In the past year the elections are responsible for a large part of the deficit, but no great reduction in expenditure can be anticipated for the present year on account of the expense of the extraordinary meeting of the Council in February and the cost that will be incurred in the inspection of primary as well as of final examinations.

The Irish Branch began the present year with a cash balance of £403. Assuming its receipts from fees to be about the same as before, say £800, it ought to be able to meet its expenses without the aid this year of a grant from the General Council, whose expenditure will therefore benefit by this reduction The Irish Branch will, it is hoped, be able to effect some reduction in its office expenses in the immediate future.

Table E shows that the assets of the Branch Councils have decreased by £1008 12s during the past year

From Table F which shows the receipts and expenditure in connexion with the Pharmacopœia, it will be seen that the debit balance of £228 8s. 7d. brought forward at the close of 1900, which was the first year in which this account was kept separate, has been reduced to £112 13s. 4d. and the sale of the stock in hand, together with the profit on the sale of the Government of India Edition of the Addendum, should turn this into a credit balance at the end of the present year.

Dental Finance—Table G shows that the receipts of the dental fund were £365 5s. 9d more than its expenditure, and its assets are therefore increased by this amount

Sinking Fund.—Mr Tomes brought before the committee the subject of the Sinking Fund and handed in a statement which is printed at the end of this report

SINKING FUND.

The complications introduced into the finance of the Council by the wording of the Act render it indispensable, in order to get a clear idea of the matter to consider it in its effect upon the finances regarded as one whole and upon them regarded from the point of view of the independent funds of the several branches.

1 Taking the funds as one undivided whole

The general idea of a sinking fund is the setting aside of money annually in sufficient amount to make good in a given period of years the depreciation of a wasting security But the freehold of the premises is not a wasting security; on the contrary it will almost surely have largely increased in value before the expiration of the term and indeed is probably now worth considerably more than the cost price at which it stands in the accounts A sinking fund in any ordinary acceptation of the term is not at all called for and is inappropriate

2. Taking the funds of the branches as having independent existence.

It was urged in favour of a sinking fund that by this means in 50 years the General Council would be placed in possession of the freehold unencumbered by a mortgage while the funds of the English Branch would be retained intact by the repayment of its mortgage

This is however quite fallacious In order that it may have the money wherewith to pay the annual premium the Council has to call upon the branches for a larger annual contribution than would otherwise suffice, in the proportion of their percentage shares. Under the rates shown on the last balance-sheet the English Branch is called upon for an additional £121 in round numbers. On a 2½ per cent. table and taking Consols at par so as to be on the safe side this amounts in 50 years to no less than £11 800 so that out of the £25 000 which it is then to receive the English Branch will have provided no less than £11,800, or in other words will receive net £13,200 in discharge of its £25,000. If there were no sinking fund at all this asset of the English Branch would be as good at the end of 50 years as it is now, by the establishment of the sinking fund it loses £11,800 This is such a shockingly bad bargain that nothing more need be said from the point of view of the interests of the English Branch except that so long as the Irish Branch does not really contribute its quota but has to be subsidised out of the funds of the other branches the figures would work out even worse than these

THE SCOTTISH BRANCH.—The rate of extra contribution called for from the Scottish Branch is about £72 per annum, or on the same tables nearly £7000 in the entire period—considerably more than their present assets. But at the end of the period they will experience some advantage in no longer being called upon for their contribution towards

> the mortgage interest, at present some £240 per annum, as there will be no rent to pay in this or any other form.'
>
> THE IRISH BRANCH.—Their nominal contribution to the sinking fund is about £21 per annum, or a total of £2000 in round numbers, but, as already remarked, this seems likely not to be really provided by them but out of the subsidies which they receive.
>
> GENERAL CONSIDERATIONS.—The real effect of the sinking fund, as was pointed out by Mr. Tomes and subsequently fully endorsed by Mr. Frere's report, is a gradual transference of the assets of the branches to the General Council to the extent of £25,000. This is not provided for under the Act and may be *ultra vires*, but it is not worth while to labour this point What is of more practical importance is that by the sinking fund the Council of to-day, in face of an annual deficit of from £1200 to £1500 a year, not likely to be less for some years to come, is setting aside a sum of money for the betterment of the Council in a remote future. That, in fact, taking the Council and its branches as a whole, it may actually be placed in a better position than it is at present by the receipt of a lump sum of £25,000.
>
> Eliminating all the confusion arising from the system of accounts dictated by the Act the common sense issue amounts to this. Is it the business of the Council of to day, with financial difficulties in full sight and with an income inadequate and likely to be still more inadequate, to be making provision, not out of its surplus but as an addition to its deficits, for the Council of 50 years hence?

On the motion of Mr. BRYANT, seconded by Dr. PYE-SMITH, the report was received and entered on the minutes.

Mr. TOMES moved a motion to the effect—

> That the payments to the Sinking Fund be discontinued and that the necessary steps be taken for obtaining, according to the agreement, a refund of a proportion of the payments already made.

Dr. ATTHILL seconded the motion.

Mr. BRYANT, while recognising the force of the arguments in favour of this step, viewed the withdrawal of the sinking fund with regret.

After a short debate the motion was agreed to.

Primary Examination of the English Conjoint Board.

It was agreed, on the motion of Mr. BRYANT, seconded by Dr. NORMAN MOORE—

> That subject to the approval of the Privy Council the remuneration of the persons appointed to visit the primary examination of the Examining Board of the Royal Colleges in England be at the rate of £5 5*s.* a day with travelling and hotel expenses.

The Prevention of Personation.

The Council then went into committee for the further consideration of the report of the committee on the Prevention of Personation. This report was before the Council in committee during the last November session and certain of the proposed regulations were then dealt with. The report, however, was sent back to the committee with a view of obtaining the opinion of the branch registrars on the regulations.

Mr. HORSLEY intimated that the comments of the branch registrars had been obtained and it was agreed that they should be entered on the minutes.

The following regulation was adopted in substitution of the first regulation passed in November, viz. :—

> All forms of application for registrations duly signed and presented shall be preserved by the Registrar of the Branch Council, to whom they may be presented in such a manner as to be easily accessible for reference.

Mr. HORSLEY moved the adoption of this regulation, viz. :—

> No certificate of registration of any name on the Medical or Dentists' Register shall be given except in respect of a registered medical or dental practitioner whose name does not appear in the current printed issue of the respective Registers.

He stated that in the present state of things it was possible for a man to go into the office, put down a merely nominal fee, say he was Mr. So-and-so, and get a certificate of registration.

Sir CHRISTOPHER NIXON seconded the motion.

Sir JOHN BATTY TUKE did not think the matter was quite so simple as Mr. Horsley suggested, because there must be a statutory declaration.

Mr. HORSLEY said that the thing had been actually done with consequences of the most distressing kind.

The PRESIDENT asked the Council to consider whether this regulation would give the Council any greater security than did the existing regulations.

Mr. HORSLEY pointed out that this was in addition to the existing regulations.

Dr. MACALISTER said that during the war the authorities of the War Office had frequently required duplicate certificates and he saw no reason why the Council should not make a reasonable provision for their issue.

Mr. HORSLEY said that once a man had his name on the Register the onus of proof lay with the person who disputed his statement that he was registered.

Dr. HERON WATSON thought it quite a legitimate thing that a man should be able to get a duplicate and his impression was that the Act provided for it.

Dr. MCVAIL expressed the opinion that the regulation was unnecessarily severe.

Mr. HORSLEY said that the certificate which was issued by the office at the time of registration was only valid until the appearance of the next issue of the printed Register.

On a divison the proposed regulation was rejected.

Mr. HORSLEY moved the following motion, viz. :—

> All applications for restoration to the Medical or Dentists' Register or for registration under exceptional circumstances shall be accompanied by a statutory declaration drawn in the terms stated in the forms included in the accompanying schedule.

This motion was under discussion when the Council adjourned.

MONDAY, JUNE 2ND.

The Council resumed to-day, Sir WILLIAM TURNER being in the chair.

The General Registrar.

In the absence of Mr. H. E. Allen, Registrar, Dr. MACALISTER, chairman on the Business Committee, called the roll and read the minutes of Saturday's sitting.

The PRESIDENT said that on Saturday afternoon the Registrar had asked leave to go home on account of the serious illness of his wife and in the evening he (Sir William Turner) had received a telegram announcing the death of Mrs. Allen. He had written to the Registrar to say that the Council would excuse his absence from the present sitting and Dr. MacAlister had kindly undertaken to act for him. Considering the long and faithful services which he had given to the Council his feeling was that they should record on their minutes an expression of sympathy with Mr. Allen.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the President was then asked to convey by letter to the Registrar an expression of the Council's sincere sympathy in the severe domestic bereavement he had sustained, it being agreed that the formal motion should form part of the minutes.

The Examinations of the Scottish Conjoint Board.

The Council proceeded to consideration of a report by the Examination Committee on the visitation and inspection of the final examinations in medicine, surgery, and midwifery for the triple qualification of the Conjoint Board of Scotland, by the visitor, Dr. Payne, and the Inspector, Sir George F. Duffey, M.D., appointed by the General Medical Council, together with remarks by the body inspected (April–July, 1901).

Mr. BRYANT, in moving that the report be received and entered on the minutes, said that the report was a very interesting one and had been very carefully drawn up. The visitor and inspector had gone through their work thoroughly, as they generally did. He did not propose to go through the report by these gentlemen or the remarks of the body visited, but he wished to call attention to the remarks of the Examination Committee on the whole. These were as follows :—

> The visitor and inspector of the Scottish Triple Conjoint Board of Scotland, having declared the final examinations for the triple qualification "to be sufficient," the Committee of Management of the Conjoint Board express their gratification at the general tenor of the report, although on certain matters of detail it was critical. The Examination Committee is satisfied with these conclusions.
>
> It is pointed out in the remarks by the body inspected that this Committee of Management of the triple Board has, since the date of the last inspection, discontinued—what this Council then condemned—the methods of allowing candidates to enter for the final examination in divisions or single subjects, although it is necessarily still permitted in the case of candidates who passed the second examination of the Board before August, 1896. It will be satisfactory to this Council when the practice has been entirely discontinued by those bodies who still permit it.
>
> The visitor and inspector point out at p. 8 of their report that in the Edinburgh written examination, as soon as the candidates took their seats, three sets of printed questions were given to each—viz., one in medicine, one in therapeutics, and one in surgery and surgical anatomy—and that four hours were allowed to write answers to the eleven questions assigned, the candidates using their own discretion in apportioning the time among the three papers. The committee is, however, informed that this practice is not always followed.
>
> At p 18 of the same report it was recorded that at the Glasgow written examination, instead of three papers of questions in two or more different subjects being given out simultaneously, they were given out singly, and a definite time was allotted for each paper. This committee suggests that the practice in Glasgow should be adopted at the examination in Edinburgh.
>
> At neither examination was the average time (half an hour) recommended by this Council for answering each question allowed. In such important subjects as medicine, surgery, and midwifery, the full time

of half an hour should be allowed for the answering of each question, although in less important subjects the rule possibly need not be so binding.

The clinical examinations in Edinburgh and Glasgow, including the examination of patients and the chemical and microscopical examination of urine and other specimens, were approved by the visitor and inspector, and it is clear to this committee that upon the whole they were well arranged. Failure in clinical medicine or surgery excludes from the oral examination in the same and allied subjects.

In Edinburgh each candidate in medicine was examined on two patients (p. 11) by one or other of the two examiners and where doubt existed the candidate was given a third. In surgery, however, each candidate was required to examine one patient only (p. 12) and was directed to mark on a patient the lines of incision for two operations. The candidate was subsequently examined upon the clinical case and also upon the assigned operations for about 20 minutes, and later on upon the names, uses, and modes of employment of surgical instruments and appliances.

At Glasgow the clinical examination in medicine differed from the one at Edinburgh in a written report of one case being required from each candidate and in the examination being conducted throughout in the presence of and by both of the examiners (p. 19) In surgery each candidate took notes of one case for which he was allowed 10 minutes and was orally examined upon two others; he was likewise examined in surgical anatomy and the uses and application of splints and instruments. The examination was pronounced by the visitor and inspector as an excellent one, but this committee is of opinion that 10 minutes for examining and reporting a clinical case is quite inadequate.

The Examination Committee would suggest that the Board of Management should arrange that in future every candidate at this clinical examination should be examined on at least three patients and that two examiners should together throughout conduct the clinical examination. To test a candidate in clinical surgery upon one case is insufficient.

The visitor and inspector state that "the plan of sending a schedule round with the candidate at each part of the examination" (p. 39), which contains not only the subjects upon which the candidate has been examined, but also the number of marks gained by him at each preceding part of the examination, is not a good one. This committee regard such a schedule, which carries out the first purpose, to be an essential aid to the examiners, but can see no good result to be gained by the second purpose, for by such an arrangement a too sympathetic examiner may be induced, in order to enable a candidate to pass, to give marks in excess of those he would have given when estimating only the value of the part of the examination in which he was concerned.

The absence of an examination in operative surgery is in the opinion of this committee greatly to be regretted. It is said to arise from difficulties connected with the working of the Anatomy Act.

The history of the oral examination of one candidate in surgery as described in pp. 16 and 17 of the report and commented upon by the body inspected on p. 41 is regrettable. This committee trusts that such an occurrence has been exceptional. The marks decided on by the two examiners engaged at the time should be arrived at with judicial care and given as their final judgment. It is to be regretted that the visitor and inspector were both absent at the re-examination of this candidate.

Dr. **NORMAN MOORE** seconded the motion.

Dr. **HERON WATSON**, referring to the last paragraph of this report, stated that he had received a letter from Mr Cotterill, one of the examiners who had had to do with the examination of the candidate alluded to, explaining that Dr. Barlow, his colleague, and he had for a time had doubts whether the candidate should be "referred" in surgery or not. They, however, had agreed on a number of marks to allow him. The whole Board of Examiners thought he should be re examined. Dr. Barlow had declined to assent to re-examination. But he (Mr. Cotterill) had undertaken re-examination and the results were such that the Board expressed the opinion that the candidate should be passed He (Mr Cotterill) was of opinion that the man did well enough to pass, though he did not express that opinion at the time the examination was going on.

Sir **HECTOR CAMERON** said that he had no personal knowledge of this matter but he had heard it discussed. His information was that Mr Cotterill and Dr Barlow examined the candidate in question. They had, no doubt, some difference of opinion, but after discussion they agreed to allow him 45 points—50 being the minimum pass number. On the matter coming before the general Board of Examiners somebody said, "Well, he wants only another five marks in surgery, let us re-examine him." To this Dr Barlow objected. However, it was arranged that he should be re-examined, but by that time the candidate had left and so also had both visitor and inspector. Later the candidate was re-examined and passed He believed that was what occurred, but the incident was not one that he could honestly say he approved of. It was not in accordance with the rule of the Conjoint Board to permit the re-examination of any candidate in regard to whose work at an examination both examiners had agreed upon the number of marks to allow. If there had been disagreement between the examiners the Board might, as they usually did in such cases, have ordered re-examination.

Dr. **MACALISTER** pointed out that the report stated that the number of marks awarded was not 45 but 40.

Sir **HECTOR CAMERON** had repeated only what he had heard.

Dr. **PAYNE** said that whether the marks given were 40 or 45 they were below the pass number, and the remarks of Sir Hector Cameron simply confirmed the report of the visitor and inspector.

Mr. **BROWN** hoped it would be understood that the General Council could not tolerate procedure of the kind under discussion. If a candidate was rejected he must regard it as a very serious matter, indeed, if that candidate by some means or other was passed without being sent back for a further period of study. The minimum marks were not sufficient for a pass, but when a candidate did not reach even the minimum he regretted that any examining board should allow him to pass.

Mr **HORSLEY** asked Dr. Payne why he had reported that the examination was "sufficient." The General Council was the only body to declare an examination "sufficient."

Dr. **MACALISTER** pointed out that the Medical Acts laid it down that there might be an opinion expressed by the inspector as to the sufficiency or insufficiency of the examination.

Dr **PAYNE** said that he had reported in accordance with what he believed it was his duty to report. When he applied the word "sufficient" he did not mean that the examination was perfect but in the ordinary sense "sufficient."

Sir **WILLIAM THOMSON** thought that Mr. Horsley was much too particular and defended the visitor and inspector's use of the word "sufficient." In his view, although the examination was not a perfect one, it was yet "sufficient" in the view of the visitor and inspector. It might have been imperfect in certain particulars but that did not destroy the sufficiency of the examination.

The motion to receive the report and enter it on the minutes was then agreed to and it was also agreed to adopt the report of the Examination Committee on the report.

The **PRESIDENT**, in answer to Mr. Brown, stated that when the three years' cycle of inspection was completed it might be that the report, with all the rest, would be considered in committee of the Council.

The Examinations of the Royal University of Ireland.

Mr. **BRYANT** read the following report by the Examination Committee on the Visitation and Inspection of the Final Examinations in Medicine, Surgery, and Midwifery of the Royal University of Ireland, held in October, 1901, by the Visitor, D. C. McVail, M.B., and the Inspector, Sir George Duffey, M.D., appointed by the General Medical Council, together with remarks by the body inspected (May, 1902):—

The visitor and inspector were of opinion that all the arrangements made for the final examination were excellent. There were 35 candidates, including one woman, and 13 examiners drawn from many different quarters.

At the clinical, oral, and practical examinations the candidates are known by their names, but in marking the answers to the written examination and at the final meeting of all the examiners to determine the result of the examination the numbers only of the candidates are before the examiners

In the written examination the questions given were numerous and sound—about six in each subject; all had to be attempted and plenty of time was allowed for each paper. The visitor and inspector were well satisfied with the marks that had been awarded by the examiners to the papers and were gratified to observe that the majority of the candidates showed an ability to write prescriptions in full Latin with accuracy as to dosage and with a grammatical correctness which is, unfortunately, far from being general at final examinations elsewhere.

The clinical examinations are held in the medical and surgical wards of the general hospitals of Dublin. The candidates are divided into groups of 12.

In medicine two only of the three examiners take part in the examination.

Each examiner had charge of six candidates in one ward and each candidate was in the first instance required to write on a form supplied a report of one case He was subsequently examined on a second and third case by one examiner and on two or three other cases by the second. On the reported case the candidate was interrogated by the examiner and in most cases required to repeat his physical examination of the patient before the examiner to demonstrate to him the signs elicited and to explain their significance.

The examination was evidently a good one although care is wanted to prevent a candidate being examined by the second examiner on cases of the same disease as he had been examined on previously by the first

The clinical laboratory work was well arranged and carried out.

In surgery the clinical examinations were essentially good and practical and there were said to have been an ample number of suitable cases. But no written report of a case was required as in the medical clinical examination but each candidate was examined on two cases by one examiner It is not quite clear to this committee why more than two cases were not utilised; it would seem only to be right to raise this part of the examination to the level of that of medicine, in marks as well as in cases

The examination on ophthalmology was all that could be wished. That on operative surgery was well conducted.

The oral examinations were well reported upon by the visitor and inspector and particularly the one on pathology. This committee would have been pleased to know whether pathological specimens were utilised freely in the medical and surgical examinations.

The visitor and inspector call attention to the fact that in the last report (Vol. xxx, Appendix viii., p. 62) it was suggested that the examination in clinical medicine might be conducted with more efficiency and with less delay by an alteration in the details of the examination and that the remarks made in that report appear still to hold good. They suggest some arrangements by which these changes might be effected and the Examination Committee trust that the authorities of the University will take them into early consideration. With respect to the surgical examination they call the attention of this committee to the fact that the recommendation of the General Medical Council that "a candidate should not be orally examined except in the presence of two examiners" is not observed. They close their carefully-worded report by stating their opinion that the final examinations in medicine, surgery, and midwifery of the Royal University of Ireland are "sufficient."

The remarks of the body inspected are quite satisfactory to this committee. They agreed to recommend "that in future the clinical examinations in medicine should be conducted by three examiners in medicine, instead of by two only, as heretofore"; that the recommendation of the General Medical Council, "A candidate should not be orally examined except in the presence of two examiners," be extended to the oral examination in surgery, and from the tone of their remarks are prepared to consider carefully the other criticisms contained in the report of the visitor and inspector.

The committee of the body inspected recognise the strict and thorough character of the inspection and express their appreciation of the courtesy shown by the visitor and the inspector.

The Examination Committee are pleased with this appreciation of the work, which has been evidently well done, and recognise in these periodical visitations a power which cannot prove otherwise than good in the influence of this Council.

He (Mr. Bryant) moved that the report be received and entered on the minutes.

Dr. NORMAN MOORE seconded the motion.

Dr. MCVAIL, asked by the PRESIDENT if, as visitor, he had anything to say, said that he had looked upon the work with great pleasure. The examination was one of the most admirable that he had knowledge of. It was conducted thoroughly and efficiently with regard to the interest of both the students and the University, and he was quite convinced that any man who took his degree in the Royal University was a man who had been adequately taught and adequately examined.

After some remarks by Sir CHRISTOPHER NIXON, who assured the Council that the Royal University of Ireland, always anxious to comply in every respect with the requirements of the Council, had made arrangements to get rid of defects pointed out by the visitor and inspector, the motion to receive the report and enter it on the minutes was agreed, and so also was the further motion, that the Examination Committee's report on the report be adopted.

The Council went into *camerâ* "to receive a statement from the Examination Committee in regard to the inspection in 1901 of the examinations of the University of Dublin." On the readmission of the public

The PRESIDENT said: The Council has authorised the visitor and inspector of the final examination of the University of Dublin to complete their inspection at the November examination.

Executive Committee.

A ballot resulted in the election of the following members to form the Executive Committee: England—Mr. Bryant, Dr. Payne, Dr. MacAlister, and Dr. Pye-Smith; Scotland—Dr. Heron Watson and Sir William Gairdner; Ireland—Dr. Atthill and Sir Christopher Nixon.

Penal Cases Committee.

The following members were chosen by ballot to form the Committee on Penal Cases—namely, England: Mr. Bryant, Mr. Tomes, Mr. Horsley, and Dr. Windle; Scotland: Dr. Heron Watson and Dr. Bruce; Ireland: Sir Christopher Nixon and Sir William Thomson.

The PRESIDENT explained that the only alteration in the composition of the committee was that Dr. Windle had been selected for the vacancy caused by the retirement of Dr. Glover.

Students' Registration.

Sir HUGH BEEVOR, on behalf of the Students Registration Committee, presented a report on exceptional cases and on the approval of certain recognised teaching institutions. He moved that it be received and approved and entered on the minutes.

Dr. MACALISTER seconded.

Dr. NORMAN MOORE called attention to the following paragraph in the report:—

> An application to be registered and antedated under exceptional circumstances:—On behalf of T. T. O'Farrell, who had passed the preliminary examination of the Irish Conjoint Board and had begun medical study at Stonyhurst College in September, 1901, requesting that he might be allowed to register and antedate to the time of commencement of medical study. Resolved: That Mr. O'Farrell be informed that Stonyhurst College has not been approved by the Council as a place for the commencement of medical study.

He thought this resolution of the committee's did an injustice to Mr. O'Farrell; it was not a proper answer to make by this Council because the Council had not taken any special pains to satisfy itself that the institution in question possessed sufficient teaching powers. He moved as an amendment to the committee's resolution—

> That Mr. O'Farrell be informed that the Council will make inquiry and if it should be found that Stonyhurst College is provided with laboratory appliances and teachers necessary for the efficient commencement of medical studies his application will be acceded to.

Stonyhurst College, he said, was not a grammar school and it was to be considered on quite a different footing. It had been inspected on two occasions by the Royal College of Surgeons of England and he knew that it had two teachers for physics with laboratory appliances and that there were teachers for chemistry and biology who were furnished with laboratory appliances. In addition, there was a natural history museum of general value. He was not urging that the Council should "recognise" this institution, but he thought the Council was putting itself into a false position by refusing to approve of a school in regard to which they had made no inquiry.

Sir CHRISTOPHER NIXON, in seconding the amendment, said that Dr. Moore's proposal did not commit the Council to an absolute recognition of Stonyhurst. This college, he believed, was recognised by the Conjoint Board, but hitherto it had not come up to the requirements of the Council. If, however, it could be shown that it had sufficient means to give adequate instruction it would be a pity to refuse it recognition.

Sir WILLIAM THOMSON asked what Dr. Norman Moore meant by "inquiry."

Dr. NORMAN MOORE did not wish to employ other than the ordinary means of getting information. If the Council asked him to supply a report he should ask the Conjoint Board if they would lend him their report for the purpose. But he thought the Council might write to Stonyhurst itself and he had no doubt that any information furnished in reply would be trustworthy.

Dr. WINDLE said that Stonyhurst College was a school and certain parts of the scientific teaching power and appliances were used for the lower division of the institution. He should strongly oppose the amendment, for he thought that it was trying by a side wind to override the Council's decision in respect to scientific institutions; and if it were adopted it would in the course of time lead to the Council's visitation and inspection of all such schools.

On a division the amendment was supported by only eight votes and was declared to have been lost, and the motion to receive and approve the report was agreed to.

The Public Health Diploma.

Dr. BRUCE presented a report by the Public Health Committee on a proposed amendment to the resolutions of the Council in regard to diplomas in public health. This report showed that in December last a section of the report of the Public Health Committee was referred back to them for reconsideration. That section was in the nature of an amendment to Rule (3) of the resolutions of the Council of Dec. 5th, 1900, as regards diplomas in Public Health, which reads as follows: "Every candidate shall have produced evidence that after obtaining a registrable qualification he has during six months, of which at least three months shall be distinct and separate from the period devoted to laboratory work as required under Rule (2), been associated day by day in the duty, routine and special, of public health administration under," &c. The precise alteration recommended was the substitution of *three* months for *six* months of outdoor or practical sanitary work, under the personal supervision of a medical officer of health duly qualified to impart such instruction; with the view of substituting a three months' course of lectures in sanitary law and other subjects cognate to the duties of a medical officer of health, such course to run concurrently with laboratory study. The committee have ascertained, as regards outdoor work, that a period of more than three months under present circumstances is impossible to secure in many cases. They consider, therefore, that it is imperatively necessary that the student should give during this period his whole time and attention sedulously to his duties. On the other hand, it seems to the committee that if the period of training be reduced to three months, the balance of the six months should be allotted to classes in sanitary law, vital statistics, and practical demonstrations in sanitary engineering. Of the advantages to be derived from such a systematic course there can, the committee consider, be very little doubt. The principles underlying sanitary law, vital statistics, and hygiene require to be stated and explained. On the other hand, demonstrations in connexion with arrangements for dealing with sewerage, the nature and use of disinfectants, the sanitary principles in the construction of dwelling-houses, the mechanism and use of refuse destructors, and the storage and filtration of water-supplies, with a moderate amount of knowledge of engineering methods, would prove of the greatest advantage to the student of public health. The committee summarised their views as follows :—

1. In the opinion of the committee at least three months' thorough training in outdoor work should be absolutely insisted upon, apart from all other kinds of teaching.

2. That the medical officer of health should be required to certify that the student has had sufficient opportunities for acquiring a thorough training in practical sanitary work and *that to his knowledge the pupil has honestly taken advantage of these opportunities.*

3. A course of lectures on the principles and practice of hygiene, vital statistics, and sanitary law *may* be substituted for the remaining three months of the six presently set aside for outdoor work, but this is merely in the nature of an option and is not meant to interfere with the present rule as to outdoor work where the medical officer of health conjoins it with teaching.

It was resolved that the report so far should be received and entered on the minutes, and the Council proceeded to consider proposed alterations in the resolutions and rules adopted in December, 1900. The first of these changes was the deletion from Rule 3 of the words "been associated day by day in the duty, routine and special, of public health administration, under the supervision of ——," and the putting in their place words of a more elastic interpretation —viz., "been diligently engaged," &c.—so as to make the complete rule, as revised, read as follows :—

3. Every candidate shall have produced evidence that, after obtaining a registrable qualification, he has during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Rule 2) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration, under the supervision of ——.

Dr. PAYNE remarked that the Medical Board which he represented took "day by day" as a stumbling-block and he was glad that the committee had found a way to get rid of it.

Dr. MACALISTER mentioned that the "day by day" part of the rule had caused much difficulty in interpretation. The substituted words would, he thought, meet all practical requirements and he believed there would be no longer any misapprehension about the meaning of the rule.

On the motion of Dr. BRUCE, seconded by Dr. NORMAN MOORE, the alteration of the rule was agreed to.

Dr. BRUCE then proposed the following as a second ⁂ note to Rule 3 :—

⁂ The period may be reduced to three months in the case of any candidate who produces evidence that, after obtaining a registrable qualification, he has during three months attended a course or courses of instruction in sanitary law, sanitary engineering, vital statistics, and other subjects cognate to sanitary study and work, given by a teacher in the department of public health of a recognised medical school.

Objection was taken that this would cut down a 12 months' curriculum to nine months.

Dr. MACALISTER said that the curriculum at present was a nine months' one and the proposed note simply allowed a rearrangement of the time in which certain things must be done. The irreducible minimum was nine months.

After further discussion the proposal was adopted in this form :—

⁂ Provided that the period of six months may be reduced to a period of three months, which shall be distinct and separate from the period of laboratory instruction under Rule 2, in the case of any candidate who produces evidence that, after obtaining a registrable qualification, he has during three months attended a course or courses of instruction in sanitary law, sanitary engineering, vital statistics, and other subjects bearing on public health administration, given by a teacher in the department of public health of a recognised medical school.

Dr. BRUCE next asked the Council to add the following words :—

⁂ Provided also that a registered practitioner of not less than five years' standing may be exempted on cause shown from the regulation as to outdoor work if he produce evidence that he has acted for at least six months as a bona fide medical officer of health or if he belong to H. M. service in the navy or army, the Indian Medical Service, or the public service of any of the colonies.

Dr. MCVAIL objected to this proposal because he did not think the committee had agreed to the exemption of officers of the army and navy, let alone the others now included.

Dr. MACALISTER thought that if put into operation this regulation would do great harm, because it would tend to reduce the leave that officers serving abroad might obtain to come home in order to go through the curriculum and it would open the door to men who might pass one day, and on the strength of having passed leave the army next day, leaving, moreover, without having had anything whatever to do with sanitary administration in order to undertake sanitary work.

Dr. BRUCE said that he was, of course, in the hands of the Council but personally he was quite ready to withdraw the proposal.

The proposal was withdrawn.

Dr. BENNETT proposed to amend the existing Rule 4— viz. :

4. Every candidate shall have produced evidence that, after obtaining a registrable qualification, he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration—

by deleting all the words after the word "diseases."

Dr. NORMAN MOORE, in seconding, said that in London it was extremely difficult to obtain opportunities for instruction in the methods of the administration of a fever hospital. As a matter of fact, in the greater part of the metropolis the regulation was unworkable and he thought that no harm would ensue from its entire omission.

Dr. MACALISTER stated that the regulation had been adopted after a great deal of consideration, and if it remained practically unworkable that was the fault of the bodies who granted public health diplomas because they had not sufficiently pressed the metropolitan hospital authorities to afford the necessary facilities.

Dr. PAYNE said that when he was speaking of this difficulty in London to Mr. Power, that gentleman had remarked that so far as the Asylums Board was concerned it was a difficulty that would easily be got over.

Dr. BRUCE had not heard that and he wished Mr. Power had been present at this discussion. His own experience of local authorities was that they were very chary in giving students the right to see what their administration was. He thought instruction of the kind was necessary and he believed that it was possible to secure it, but he questioned whether it was well to have a rule of this kind standing.

Dr. MCVAIL remembered Sir Richard Thorne, the late chairman of the committee, expressing the opinion that the man was not competent to do the work of medical officer who had not had a course of study in the administration of an infectious hospital. He hoped there was no chance of the rule being dropped.

Mr. BROWN must urge the Council most strongly not to tamper with this rule. It was most important that men should be thoroughly instructed in sanitary work and this rule must operate in the direction of securing that.

Dr. MACALISTER moved that the rule be adhered to.

Dr. MCVAIL seconded.

Dr. BENNETT'S proposal was modified so as to substitute the words he originally proposed to omit by the words "in view of the acquisition of a knowledge of the methods of administration."

It was agreed to treat this proposal as an amendment, and on being put to the vote it was supported by so few members that the President declared it to be lost. Rule 4 consequently was retained without alteration.

Adjustment of the amended report was deferred and the Council adjourned.

FOREIGN UNIVERSITY INTELLIGENCE.—*Freiburg :* Dr. Ernst Roos, *privat-docent* of Medicine, has been promoted to an Extraordinary Professorship.—*Giessen :* Dr. Johannes Pfannenstiel of Breslau has been appointed to succeed the late Professor Löhlein in the chair of Midwifery and Gynæcology.—*Göttingen :* Dr. Bendix has been recognised as *privat-docent* of Medicine.—*Heidelberg :* Dr. Kehrer, Professor of Midwifery and Gynæcology, is about to retire.—*Leipzig :* Dr. Saxer, *privat-docent* of Pathological Anatomy, has been promoted to an Extraordinary Professorship.—*Turin :* Dr. Arnaldo Fumagalli of Pisa has been recognised as *privat-docent* of Ophthalmology.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE annual general meeting of the governors of the Royal Medical Benevolent College was held on May 30th, at the office in Soho-square, London, W., the treasurer of the institution, Dr. O. HOLMAN, being in the chair. The scrutineers announced the result of the voting to be as follows:—

PENSIONERSHIPS.

1. Owen, Fanny E.	10397	5. Matthews, Lucy E.	4939
2. Sheppard, Margaret M.	9347	6. Wilson, Fanny W.	4339
3. Jones, Caroline M.	9319	7. Nolan, Sarah	3295
4. Johnson, Charlotte	7492		

FOUNDATION SCHOLARSHIPS.

1. Curry, Wilfred L.	8710	4. Cowan, John A.	7325
2. MacNaught, Gerald K.	8165	5. Leigh, Reginald H.	5625
3. Wallington, William T.K.	8048	6. Sewart, John H.	4483

MORGAN ANNUITIES.

1. Rymer, Matilda S.	7649	3. Wilcocks, Ann	3578
2. Thackthwaite, Emma	3718		

In opening the proceedings, Dr. HOLMAN referred to the lamented death of Dr. John Lumsden Propert, a son of the Founder of the College, and proposed a motion of condolence with Mrs. Propert and her family which was seconded by Sir JOSEPH FAYRER and carried unanimously.

In reference to the report for the past year Dr. WINSLOW inquired whether the Council could see its way to have the name of the institution altered to "Epsom College." In replying, Mr. STAMFORD FELCE, the chairman of the Finance Committee, stated that the Council had given most careful consideration to the matter, but it had come to the conclusion that it was inexpedient to make a change, in view of the fact that money was absolutely necessary for the charitable side of the institution, and if the name of the institution were to be altered as indicated it was highly probable that important legacies such as those which had recently been received would no longer be left to the College.

The following were elected members of the Council: Mr. G. C. Croft, Sir Joseph Fayrer, Dr. Latham, Dr. A. C. Latham, Dr. Needham, Rev. E. W. Northey, Mr. H. W. Page, Mr. Pollard, Dr. F. Taylor, and Dr. Thomas Buzzard. Dr. Galton was elected a vice-president in recognition of his having collected £1000.

A vote of thanks was proposed by Sir JOSEPH FAYRER to the chairman, a brief reply from whom brought the proceedings to a close.

ASYLUM REPORTS.

Nottingham City Asylum (Annual Report for 1901).—The average number of patients resident during the year was 704, comprising 343 males and 361 females. The admissions during the year amounted to 205—viz., 128 were males and 77 females. Of these 188 were first admissions. Mr. Evan Powell, the medical superintendent, states in his report that there were 30 private patients in residence during the year. Among the admissions a large proportion of patients presented no prospect of recovery. Thus 18 of them were subjects of senile mental disease, eight were epileptic, and 18 were general paralytics. Among the general paralytics there was a much larger proportion of females than usual. Among the causes of insanity in the patients admitted hereditary predisposition was ascertained in 25 cases, alcoholic intemperance in 19, and mental stress of one kind or another in 29 cases. 50 of the admissions were males suffering from chronic insanity, received under contract from London and East Sussex to fill up vacancies afforded by the opening of the new wing in the institution. The number of patients discharged as recovered during the year amounted to 67—viz., 25 males and 42 females, or 9·5 per cent. of the average number resident. The deaths during the year amounted to 74—viz., 37 males and 37 females, or 10·4 per cent. as calculated on the same basis. Of the deaths two each were due to epilepsy, senile decay, and colitis, four to cerebral softening, four to cardiac disease, five to cerebral atrophy, six to renal disease, nine to phthisis, 27 to general paralysis of the insane, and the rest to other causes. The cause of death was ascertained by post-mortem examination in 70 out of the 74 cases. Of the two cases of colitis one was a patient admitted from a London asylum who died from the disease a fortnight after admission, so that he had probably contracted the disease before admission. The other case was that of a patient who had been in the asylum for some years. "Colitis," adds Mr. Powell, "is said to be in a large measure due to overcrowding; if this be so it is curious that it made its appearance with us some time after the opening of the new wings and when our accommodation was ample. It is undoubtedly an infectious disease, so that every precaution was taken to prevent its spread, and with satisfactory results, as we have not had another case." The new block for male epileptics was completed and occupied in March. The Commissioners in Lunacy state in their report that the wards were bright and cheerful, the dormitories and bedding clean and in good order, the patients neatly dressed and orderly in their behaviour, and the medical case-books well kept. The weekly charge for patients remains the same as in the previous year—viz., 10*s.*

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON Thursday, July 3rd, a meeting of the Fellows of the College will be held for the election of four members of Council. Three of the members retire by rotation—namely, Mr. Reginald Harrison, Mr. Howard Marsh, and Mr. J. Hardie. The fourth vacancy is due to the death of Sir William Mac Cormac.

The following list of the 23 members of Council gives the date at which each member will retire; the date of the first election is given in every case in which the member has been elected to the Council more than once:—

Retire in 1909: Professor A. W. Mayo Robson, Leeds Infirmary (first elected 1893); Mr. W. Watson Cheyne, King's College Hospital; and Mr. Clement Lucas, Guy's Hospital.

Retire in 1908: Mr. Alfred Cooper (first elected 1892); Dr. J. Ward Cousins, Royal Portsmouth Hospital (first elected 1895); and Mr. A. Pearce Gould, Middlesex Hospital.

Retire in 1907: Mr. T. R. Jessop, Leeds General Infirmary (first elected 1891); and Mr. H. W. Page, St. Mary's Hospital.

Retire in 1906: Mr. F. Richardson Cross, Bristol Royal Infirmary; Mr. Henry Morris, Middlesex Hospital (first elected 1893); and Mr. John Langton, St. Bartholomew's Hospital (first elected 1890).

Retire in 1905: Mr. H. G. Howse, Guy's Hospital (first elected 1889); Mr. Edmund Owen, St. Mary's Hospital; and Mr. Rickman J. Godlee, University College Hospital.

Retire in 1904: Mr. Thomas Bryant, Guy's Hospital (first elected 1880); Mr. T. Pickering Pick, St. George's Hospital (first elected 1888); and Mr. J. Tweedy, University College Hospital (first elected 1892).

Retire in 1903: Mr. A. Willett, St. Bartholomew's Hospital (first elected 1887); Mr. H. T. Butlin, St. Bartholomew's Hospital; and Sir F. Treves, London Hospital.

Retire in 1902: Mr. Reginald Harrison (first elected 1888); Mr. Howard Marsh, St. Bartholomew's Hospital (first elected 1892); and Mr. J. Hardie, Royal Infirmary, Manchester.

We understand that Mr. Howard Marsh intends to offer himself for re-election but that Mr. Harrison and Mr. Hardie will not stand again.

At present there are eight candidates in addition to Mr. Howard Marsh. These are Mr. H. H. Clutton of St. Thomas's Hospital; Sir W. H. Bennett and Mr. C. T. Dent of St. George's Hospital; Mr. J. H. Morgan of Charing-cross Hospital; Mr. C. H. Golding-Bird of Guy's Hospital; Mr. C. Mansell Moullin of the London Hospital; Mr. J. Bland-Sutton of the Middlesex Hospital; and Mr. Jordan Lloyd of Birmingham.

There may be other candidates, as there is still time to apply. Applications must reach the secretary by Monday, June 9th.

ANNUAL MEETING OF FELLOWS.

The annual meeting of the Fellows will be held on Thursday, July 3rd, at 5.30 P.M., after the conclusion of the election to the Council. Any motions will be considered of which notice has been sent to the secretary not later than June 12th. Unfortunately, on the last five occasions on especially in middle life, as the result of some definite cause. It is not clear how far these are due to induced defect of life. The degeneration may be the result of the presence in the blood of some material which is able to enter into the constitution of the nerve elements but is not adequate for their proper functional or structural maintenance. They may slowly recover if the supply of the noxious matter ceases. Arsenical neuritis is an example. Arsenic seems capable of taking the place of phosphorus in metabolic changes of nutrition but its presence deranges function and also structure, so that degenerative change is the result. The alteration begins where vitality is weakest, at the extremities of the nerves furthest from the nutritional centre, the cell; the energy of this may ultimately be impaired, but we have not evidence that the primary influence is exerted on this or that the process consists essentially in a failure of vital energy, that it is a true abiotrophy. The same statements may be made with regard to alcoholic neuritis, since the same process occurs in this.

The most common neuronic degeneration of the middle period of life is tabes. This, as you know, must be ascribed to the influence of a post-syphilitic toxin. But it occurs so long after the primary disease and at such a variable interval of years that the question arises—Is the affection of the nerve elements due to the constant presence of the toxin in the system in varying quantity and varying degree of toxic power, or has a transient toxin an influence in reducing future vital endurance? In the latter case it may be regarded as acquired abiotrophy. Each hypothesis has difficulties, but neither is quite inconceivable. On the whole, I think the first is that which best explains the facts of the disease. The analogous toxin of which we know most—that which causes diphtheritic paralysis—has been proved by Professor Sidney Martin to be due to a change in the chemical constitution of albuminoses caused by a ferment-like material which the organisms in the throat produce. The toxin varies in its character, to judge by its different effects, and it is noteworthy that it may sometimes act on the same neurons as are affected in locomotor ataxy and give rise to the same symptoms. It is conceivable that such a change in the chemical constitution of albuminous substances once set up may continue and the toxin may be constantly produced in varying amount and varying toxic power, its formation being modified from time to time by other influences of which we know nothing. In the processes concerned in the production of excess of sugar we have an example of the persistence of the derangement of a chemical process and its gradual increase if not restrained, and although the analogy is not very close (since sugar is a normal product) it illustrates that such disordered chemical action may be enduring. The occasional rapid increase in the symptoms of tabes, such as may bring a patient from a stationary slight degree to the most extreme disability in a few days, is better explained by the sudden production of a poison of greater power than by the sudden reduction of the resistance of structures the vitality of which is impaired. The same conclusion seems suggested by the great improvement which we meet with in some cases. A man came in here about two years ago who had had symptoms of the first stage for some years and then in the course of a few days the ataxy increased to such a degree that he was not able to stand from the extreme incoördination. Retention of urine had developed and cystitis had set up a suppurative orchitis. Yet this patient gradually improved until he could walk without much unsteadiness before he left the hospital and now he can walk well for eight or nine miles. Unfortunately, improvement does not always occur in the case of rapid exacerbation. There is one tabetic process the course of which is more uniformly progressive, so much so, indeed, as to resemble closely the effect of reduced vitality—the atrophy of the optic nerves. But even in this we meet with cases which become arrested, usually as the result of treatment. The significance of this fact we cannot discern or even wisely speculate about. Arrested improvement from treatment occurs in other slow degenerations which occur during the middle period of life, some of them are met with occasionally as the sequelæ of syphilis, but they may occur without obvious cause or as the result of exposure to cold, or they seem to be due to the toxin of some other specific disease. The nature of these also is doubtful. Some of the progressive muscular atrophies of middle life resemble the senile form we have just considered in their slow commencement and gradual extension and increase, and sometimes in the absence of a cause. Yet they differ in being more amenable to treatment. There is a considerable prospect that such cases will be permanently arrested. But even in the cases after syphilis it is not by anti-syphilitic treatment that good is done but by the hypodermic injection of strychnia. In one typical case the malady commenced just after a course of treatment at Aix, but the permanence of the arrest is shown by the fact that it has now been absolute for about 12 years. In another case, more advanced but also arrested, the treatment was commenced after a rapid increase which occurred during the administration of iodide of potassium. This treatment has not the same influence in the senile abiotrophic form.

That terrible malady, general paralysis of the insane, seems, often at least, to be due to the same cause as tabes, symptoms of which are so often associated, and seems to be of the same degenerative nature, produced no doubt in a like way. That which has been said of tabes applies to it also, and that which has been said of the secondary processes may explain the inflammatory changes often met with. But here we are on uncertain ground. Those cases which belong to the type which is recognised as most characteristic seldom fail to go on to death. Here also the pathological relation of the morbid process to its cause is quite obscure.

Just as the simple baldness which develops in early manhood may also come on at any period in adult life and in any degree, so the family abiotrophies which usually commence early in adult life or in childhood may show themselves later. In the families in which some members suffer early, in other members the same symptoms may occur only during middle life—a fact which we can understand by the conception that the degree of vital energy in such cases is greater, the vital endurance is such as to persist longer. Yet the occurrence of both in the same family shows that their nature is the same and that the difference is one of degree.

These conceptions I hope may help you, if not to understand these processes, at least to think of them more clearly. I would especially impress upon you the fact which is illustrated by the lad whom I have shown you—the sporadic occurrence of these abiotrophic diseases. Their nature is easily discerned when they occur in groups which have the tie of consanguinity but the discernment is less easy when the disease occurs in isolated form. Remember the significance in such cases of the age of the patient, the slow development of the malady, the absence of adequate cause whether an inadequate cause can or cannot be traced, and the correspondence of the symptoms to the functions of certain sets of neurons. Many cases of this kind are regarded as due to disseminated insular sclerosis, often assumed to exist when the symptoms afford no justification for the opinion and in cases in which the future course of the case negatives it. It was, indeed, written at the head of the notes of this case before I saw the patient. Remember that the symptoms of systematic degeneration are not alone ground for the diagnosis of insular sclerosis nor is the additional presence of nystagmus. Nystagmus on movement of the eyes is met with in many spinal degenerations of pure systemic type, why we do not know, but the fact deprives it of the diagnostic importance which has often been attached to it.

My object in this lecture has been to present to you the aspect of many degenerative diseases of the nervous system as a result of a defect in vitality. The two aspects of death which I mentioned at the onset are very different in our practical view. Somatic death is that against which we ever strive, which we endeavour to postpone as long as may be. The other aspect of death—the termination of life of isolated structures in the body—is to us what we call disease. It does not of necessity involve the termination of general life, but it is not less to be striven against, although the strife must often be in vain. The discernment of these diseases which we may call "abiotic," the recognition of the symptoms, *the course*, and the *conditions* which indicate them is of extreme importance. It may save you from many errors, may prevent many mistakes, both in your forecast and your treatment. We must endeavour to check their progress, for we seldom know the strength or feebleness of the tendency, or whether it can be hindered, but the discernment of the nature of these maladies will often help you. It will enable you better to perceive why treatment fails and it may save from useless prolongation of attempts to gain that which cannot be, and it may sometimes save from waste of money that can ill be spared and from the waste of hope which means only deeper disappointment.

which a meeting of the Fellows has been summoned no quorum has been obtained, probably chiefly because there have been no agenda.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF MEDICAL OFFICERS OF HEALTH

Bromsgrove Urban District.—Dr. H. Cameron Kidd continued during 1901 his energetic efforts with regard to the control of tuberculosis and a sample of milk from each dairy in the district was examined for the tubercle bacillus But the specific bacillus was not detected microscopically, culturally, or by inoculation. Dr. Kidd is most surprised at this result as he finds it difficult to believe that none of the milch cattle were suffering from tuberculosis His suspicions are probably well founded, but, as was shown in the investigations performed under the auspices of the first Royal Commission on Tuberculosis, it is extremely rare to detect the tubercle bacillus unless the udder itself is diseased, and possibly very different results might be obtained at Bromsgrove were the tuberculin test applied to the cattle, or were the milk only examined in cases where the udders were involved, indeed, perhaps the most useful measures in the present state of our knowledge are the frequent inspection of dairies and cowsheds, and the examination of the cow's udders in all cases.

Macclesfield Urban District.—Mr. J. Hedley Marsh deplores the altogether undue loss of life from infantile mortality in this borough, and the statistics for the last 12 years show that there is practically no diminution in that mortality During 1899 and 1900 the rates were 190 per 1000 births for each year, and although during 1901 the rate fell to 180 Mr. Marsh attributes this improvement to the slackness of trade which enabled the mothers to stay at home and to nurse their offspring rather than to consign them to the care of a nurse whose main object is to keep the children quiet at any cost

Exeter Urban District.—Dr. John Woodman reports that the intercepting sewers which are being constructed at Exeter are nearly completed and that nearly the whole of the sewage is being taken to the septic tanks at Belle Isle. At present the effluent from the septic tanks is apparently passing directly to the land, but when the filters are constructed such effluent will pass through the filters before passing over the land. The work which has already been performed has, we are told, very materially improved the state of the Exe

Plympton St. Mary Rural District.—Mr. S. Noy Scott reports that the council of the district has had under its consideration the question of supporting the proposed Devon Sanatorium for Consumption by means of annual subscriptions. There was, however, some doubt as to the legality of the proposed contribution and the Local Government Board was consulted in the matter Apparently no definite reply had been received at the date of writing the report, but we doubt if any objection is likely to be raised by the central authority, more particularly as the proposed sanatorium is referred to in the sense of an isolation hospital rather than as a place of cure This distinction is legally, we believe, of some importance. In any circumstances Mr. Scott advises his council not to rest content with a negative reply, but to endeavour by joint action with other authorities similarly placed to alter the Whitehall decision.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9118 births and 4710 deaths were registered during the week ending May 31st. The annual rate of mortality in these towns, which had been 17·3 and 16·6 per 1000 in the two preceding weeks, further declined last week to 16·5 per 1000. In London the death rate was 16·6 per 1000, while it averaged 16·5 in the 75 other large towns The lowest death rates in these towns were 6·5 in Wallasey, 7·3 in Smethwick, 7·5 in Handsworth, 7·6 in Hornsey, 8·3 in Newport (Mon.), 9·0 in East Ham, and 9·9 in Willesden, the highest rates were 22·9 in Liverpool, 23·0 in Salford, 23·5 in Middlesbrough, 23·9 in Burnley, 24·2 in Rochdale, 24·6 in Burton on Trent, 25·7 in Oldham, and 25·9 in Barrow-in Furness. The 4710 deaths in these towns included 505 which were referred to the principal zymotic diseases, against 516 and 531 in the two preceding weeks, of these 505 deaths 151 resulted from measles, 108 from whooping cough, 59 from small-pox, 59 from scarlet fever, 54 from diphtheria, 45 from "fever" (principally enteric), and 29 from diarrhœa. No death from any of these diseases was registered last week in Croydon, Hornsey, Hastings, Portsmouth, Norwich, Handsworth, Aston Manor, Coventry, Grimsby, or Stockport, while the highest zymotic death rates were recorded in Tottenham, Rochdale, Burnley, Barrow-in-Furness, Middlesbrough, Sunderland, and South Shields. The greatest proportional mortality from measles occurred in Bournemouth Derby, Bury, Rochdale, Barrow in Furness, Stockton on-Tees, and Sunderland, from scarlet fever in Burnley, from diphtheria in St. Helens and Middlesbrough; from whooping-cough in Birkenhead, Barrow-in-Furness, West Hartlepool, and South Shields, and from "fever" in Middlesbrough. 59 fatal cases of small pox among persons belonging to these large towns were registered last week, of these 48 belonged to London, seven to West Ham, and four to Tottenham. The Metropolitan Asylums hospitals contained 1274 small pox patients at the end of last week, against 1419, 1360, and 1344 at the end of the three preceding weeks, 251 new cases were admitted during the week, against 248, 233, and 307 in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2212, 2207, and 2236 on the three preceding Saturdays, had further risen to 2266 on Saturday, May 31st, 319 new cases were admitted during the week, against 256, 270, and 280 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 231, 216, and 237 in the three preceding weeks, further rose last week to 261, and were 15 above the corrected average. The causes of 51, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Portsmouth, Bristol, Leicester, Nottingham, Manchester, Salford, Bradford, Newcastle, and 47 other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Preston, Halifax, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·1, 19·4, and 20·3 per 1000 in the three preceding weeks, declined again to 19·3 per 1000 during the week ending May 31st, but showed an excess of 2·8 per 1000 over the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 15·2 in Leith and 15·9 in Greenock to 21·1 in Paisley and 25·0 in Perth The 624 deaths in these towns included 22 which were referred to whooping-cough, 15 to diarrhœa, 13 to measles, four to diphtheria, two to "fever," and one to scarlet fever In all 57 deaths resulted from these principal zymotic diseases last week, against 74 and 55 in the two preceding weeks. These 57 deaths were equal to an annual rate of 1·8 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 25 and 14 in the two preceding weeks, rose again last week to 22, of which 14 occurred in Glasgow, two in Edinburgh, two in Dundee, two in Aberdeen, and two in Leith. The deaths from diarrhœa, which had been 19 and 14 in the two preceding weeks, increased to 15 last week, and included six in Glasgow, three in Dundee two in Edinburgh, and two in Paisley The fatal cases of measles which had been 21 and 16 in the two preceding weeks, further declined last week to 13, of which eight were registered in Glasgow and two in Edinburgh. The deaths from diphtheria, which had been three, four, and one in the three preceding weeks, rose again to four last week and included three in Edinburgh. The two fatal cases of "fever" showed a decline from recent weekly numbers and were both recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 113, 114, and 156 in the three preceding weeks, declined again last week to 129, but were 22 above the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8 and 19·1 per 1000 in the two preceding weeks, rose again to 22·3 per 1000 during the week ending May 31st. During the past four weeks the death-rate has averaged 22·2 per 1000, the rates during the same period being 16·5 in London and 17 5 in Edinburgh. The 162 deaths of persons belonging to Dublin registered during the week under notice exceeded by 23 the number in the preceding week and included eight which were referred to the principal zymotic diseases, against 12, 13, and six in the three preceding weeks; of these, two resulted from measles, two from diphtheria, one from scarlet fever, one from whooping-cough, one from "fever," and one from diarrhœa. These eight deaths were equal to an annual rate of 1·1 per 1000, the zymotic death-rates during the same period being 2·3 in London and 1·5 in Edinburgh. The deaths from measles, which had been six, three, and two in the three preceding weeks, were again two last week. The mortality from "fever" and from diarrhœa also corresponded with that recorded in the preceding week, while that from scarlet fever showed a slight decline. The 162 deaths in Dublin last week included 33 of children under one year of age and 35 of persons aged upwards of 60 years; the deaths of infants were considerably in excess of the number recorded in the preceding week, while those of elderly persons showed a slight decline Seven inquest cases and four deaths from violence were registered; and 63, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

MAJOR C. G. WOODS retires from the service, receiving a gratuity. Dated June 4th, 1902.

INDIAN MEDICAL SERVICE.

Colonel A. Scott Reid, succeeds Surgeon-General Spencer, C.B., as Principal Medical Officer of the Punjab Command and Colonel W. McConaghey, Lucknow, takes Colonel A. Scott Reid's place as Inspector-General of Civil Hospitals in the Punjab.

IMPERIAL YEOMANRY (IN SOUTH AFRICA).

32nd Battalion: Robert John McClelland to be Medical Officer, with the temporary rank of Captain.

38th Battalion: Richard Murphy to be Medical Officer, with the temporary rank of Captain in the Army.

IMPERIAL YEOMANRY.

The undermentioned officers resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority, viz.:—

Duke of Lancaster's Own: Surgeon-Lieutenant-Colonel W. W. Wingate-Saul and Surgeon-Lieutenant L. G. S. Molloy.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain W. A. Dingle to be Surgeon-Major. Dated June 4th, 1902.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cinque Ports; Surgeon-Captain J. W. T. Gilbert to be Surgeon-Major. 2nd Devonshire: Malcolm Bell Hay to be Surgeon-Lieutenant.

Rifle: 8th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Captain John Anderson resigns his commission and is appointed Captain. 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Captain D. Stewart to be Surgeon-Major. 3rd (Morayshire) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Lieutenant D. G. Campbell to be Surgeon-Captain. 1st Dumbartonshire: Surgeon-Lieutenant T. J. Burton to be Surgeon-Captain.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

1st London: Surgeon-Captain W. N. Evans, from the 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment), to be Surgeon-Captain and to command under paragraph 55A Volunteer Regulations.

NOTES FROM SOUTH AFRICA.

Civil Surgeon Abraham Ellenbogen was reported dangerously ill from typhlitis at Cape Town on June 1st, but after an operation on the following day he showed signs of recovery and is now progressing satisfactorily.

Civil Surgeon White is reported "distinctly better."

THE FUTURE EDUCATION AND TRAINING OF ARMY OFFICERS.

Among the recommendations and suggestions contained in the report of the Committee on Military Education there is one which will commend itself, if only on hygienic grounds, to the medical profession as highly desirable—namely, that a military cadet's studies would be, as far as possible, better carried out in the open air than in class-rooms. As far as their health and physical efficiency are concerned—and these count for even more in the army and navy than they do in other walks of life—we should say that army cadets cannot be too much in the open air and too little in lecture-rooms and class-rooms or engaged in sedentary occupations. It is difficult, no doubt, to discover some method of selecting candidates for our public services other than that of competitive examinations, but so far as these are written examinations they give a very inadequate idea of the capacity and fitness of a young fellow for an army life and campaigning work. They necessarily leave out of consideration altogether qualities of character, judgment, temper, and common-sense. Provided that a candidate comes up to the physical standard required by the regulations he may, if only properly crammed, succeed in taking a high place at a competitive examination and in supplanting other and much more desirable candidates. It cannot be said that the Boers are an intellectual or a cultured race, but as far as military tactics are concerned they have taught us and every other nation a great practical lesson. A competitive examination for our future officers should, as we have always held, be competitive all round, and superior physical qualifications and efficiency in school sports and games should count for something. It goes without saying that the possession of brains as well as bodies is a necessary qualification and that everybody is the better for being well educated generally and for being specially taught and trained for any and every walk in life. In the case of the more scientific branches of the army service—such as the Royal Engineers, the Royal Artillery, and the Royal Army Medical Corps—such special training is essential; and in the case of the Royal Military Academy at Woolwich it is satisfactory to find that the committee has no particular fault to find with the system and course pursued there. It is with the Royal Military College at Sandhurst that the committee appears to be so much dissatisfied and to have expressed its belief that the military training of young officers at that institution fails to develop knowledge or to promote efficiency. Mr. Brodrick having, as we may suppose, settled on a scheme for the future Royal Army Medical Corps, will have now to occupy his attention with army educational reform.

THE UNIFORM OF MEDICAL OFFICERS OF THE YEOMANRY AND VOLUNTEER CORPS.

We have recently received inquiries from correspondents with regard to the proper "kit" for medical officers of the yeomanry and volunteer corps. The following may therefore prove of use to many of our readers:—Medical officers of yeomanry wear the uniform of their respective corps (paragraph 352, Regulations for Yeomanry Cavalry, 1898). As regards volunteers: 1. Regimental medical officers of volunteer corps wear the uniform of their respective corps, with sword and pouch-belts as for officers of the Royal Army Medical Corps, silver being substituted for gold (paragraph 917, Volunteer Regulations). 2. Brigade-surgeon lieutenant-colonels may wear either their regimental uniform or the uniform of officers holding similar appointments in the Royal Army Medical Corps (paragraph 915, Volunteer Regulations). 3. Officers of the Royal Army Medical Corps (Volunteers) will wear the same uniform as officers of the Royal Army Medical Corps, silver being substituted for gold (paragraphs 903, 909 F., 910, 893, 894, and 899). 4. Officers gazetted to volunteer infantry brigade bearer companies will wear the same uniform as Royal Army Medical Corps (Volunteers) except that the title of the company will appear on the helmet plate and shoulder strap (paragraph 851). Particulars of the uniform of yeomanry and volunteers do not appear in the Dress Regulations, but sealed patterns are kept in the department for "dress" in the War Office, where information on any point can be obtained.

The Army Rank of the Director-General of the Army Medical Service.

In connexion with the new system of army medical administration, by which, as we have previously announced, the Director-General is to occupy a more influential position in the councils of the War Office as the responsible representative of the Army Medical Department, it is satisfactory to learn that he will in future rank officially as a lieutenant-general and not as a major-general, as has hitherto been the case. It was no doubt deemed necessary to take this step in order to put the Director-General in his proper position in his official dealings with the headquarter staff and also to raise his military rank above that which is held by senior administrative officers serving under him. On these and other grounds the change is to be regarded as a desirable and wise one.

Deaths in the Services.

Civil Surgeon Birch, at St. Helena, on May 28th, from enteric fever.

Sir T. J. Gallwey has arrived at Simla and taken up his appointment as Surgeon-General of His Majesty's Forces and Principal Medical Officer of India.

Correspondence.

"Audi alteram partem."

ETHER v. CHLOROFORM.

To the Editors of The Lancet.

Sirs,—Anent the correspondence in your columns as to the relative safety of ether and chloroform, will you allow me to recall that some years ago I pointed out in your journal[1] that the only really reliable data bearing on this subject were comprised in the admirable records of the administration of anæsthetics as tabulated in the St. Bartholomew's Hospital annual reports, which go back as far as 1875. As the subject still continues to attract in an increasing degree the attention of the profession I should like to set forth the results up to date, so that, so far as the occurrence of fatalities is concerned, there should in future be no ambiguity.

With regard to *chloroform*, the hospital records for the 16 years 1875–1890 show 13 deaths in 19,526 administrations. Since then the course of events has been as follows:—

Year.	Administrations.	Deaths.
1891	2,031	1
1892	1,827	1
1893	2,524	2
1894	2,350	2
1895	2,552	2
1896	2,436	3
1897	1,939	2
1898	2,648	3
1899	2,604	3
1900	2,561	1
Total	23,452	20

Thus during the 26 years 1875–1900 chloroform was administered 42,978 times, with 33 fatalities or 1 in 1300.

During the 16 years 1875–1890 *ether* was administered 21,332 times with only four deaths. In 12,941 of these cases ether was preceded by "gas," only one fatality belonging to this category; in the other 8391 cases ether alone was given and three deaths occurred. Since this period the ether record has been as follows:—

Year.	Ether alone.	Deaths.	Ether preceded by "gas."	Deaths.	Total.
1891	866	*Nil.*	130	*Nil.*	996
1892	824	"	73	"	897
1893	1420	"	17	"	1,437
1894	931	"	701	"	1,632
1895	242	"	1,150	"	1,392
1896	189	"	1,427	"	1,616
1897	201	"	1,261	"	1,462
1898	43	"	1,872	"	1,915
1899	17	"	2,382	"	2,399
1900	43	"	2,106	"	2,149
Total ...	4826	*Nil.*	11,119	*Nil.*	15,945

Thus, during the 26 years 1875–1900 ether was administered 37,277 times, with only four fatalities, or 1 in 9319. In 24,060 of these cases ether was preceded by "gas," and only one fatality occurred. In 13,217 cases ether alone was given and three fatalities occurred, or 1 in 4405.

It follows from the foregoing that ether is a very much safer anæsthetic than chloroform (in the proportion of 1300 to 9319); but much safer than either of these agents alone is ether preceded by "gas."

I am, Sirs, yours faithfully,
Clifton, Bristol, May 31st, 1902. W. Roger Williams.

THE FEEBLE-MINDED AND CRIME.

To the Editors of The Lancet.

Sirs,—Miss Dendy's paper on the above subject in The Lancet of May 24th, 1902, p. 1460, is a valuable contribution towards the discussion of a social problem of great importance and magnitude. The views there expressed coincide very nearly with the conclusions which I have drawn from four years' work in connexion with the schools for the mentally defective under the London School Board. Important as the education of the feeble-minded is, it forms but a small, and by far the least difficult, part of the problem what to do with the feeble-minded. The work that is being done in this direction by public bodies and private individuals is, in my opinion, often largely thrown away because there exists no subsequent provision for the needs of a great number of those whom we attempt to educate.

In 1892 the London School Board first established special centres for the instruction of the mentally deficient and there are now nearly 2500 children on the rolls of these classes. Sufficient time has therefore elapsed to make it possible to form some opinion on what the future of children thus educated is likely to be. A certain number of the children passed as mentally deficient are passed out after a period of special training into the ordinary schools. These comprise largely in my experience cases of two types, the first neurotic excitable children below par mentally but without marked mental abnormality, the second stolid and apathetic children with sluggish brains but usually well nourished physically. Children of both these types do badly in the large classes of ordinary schools; they stagnate, or in the one case tend to nervous breakdown and in the other develop into hopeless dullards or truants. Under the individual training of the special classes they improve greatly and are usually able to return in time to the ordinary schools and rank henceforth as normal individuals. To these may be added another type common enough in the poorer districts—children stunted in body and mind from underfeeding and apparently incapable of learning anything. To the fact that in the defective centres, thanks to private charity, food is generally obtainable for really necessitous cases is due, I think, the striking improvement which often takes place in these cases. But the number of children returned to ordinary schools is small; I have not at present the exact statistics but they would hardly exceed 10 or 15 per cent. A few cases at the other end of the scale are excluded as imbeciles and considered only fit for an asylum.

---

[1] The Lancet, Feb. 8th, 1890, p. 317.

The large majority of the children admitted remain, however, in the special classes until they are passed out into the world. I think it may be said that all are improved and most are capable of doing work of some kind to a greater or less degree, but in very few cases can they compete with, or rank as, normal individuals. Past arrested development cannot be wholly compensated for; the adult remains in many respects a child, often with definite mental defects or at least with queer mental twists which produce exasperation in employers and despair in philanthropic friends. A certain proportion are incapable of work under ordinary conditions; if they obtain places they lose them at once. The majority, however, do obtain work. The boys seem to get employment readily and in certain kinds of mechanical work do well. But as they get older the difficulties of getting work increase; they can command boys' wages but do not become good enough to obtain those of men, and many sad histories come to the knowledge of the teachers in the schools they have left The girls obtain factory work of an ill-paid kind or small places as domestic servants which they rarely retain long. If they do not marry, and often if they do, they usually become inmates from time to time of a workhouse maternity ward. Judging by what we often observe in the parents of the children with whom we have to deal, feeble mindedness in either man or woman is no bar to matrimony, and indeed many of these defectives marry soon after they leave school with the probability, almost amounting to certainty, of transmitting a heritage of morbid mental or nervous conditions to their descendants.

As regards the question specially dealt with by Miss Dendy, the connexion of feeble-mindedness with crime, there is undoubtedly in every centre a group of cases approaching the type of the moral imbecile and characterised by instinctive tendencies to theft and other forms of immorality, but I do not think this is the case with the majority of the feeble-minded. When these drift into crime it is rather because they naturally sink into the lowest strata of society and are unduly amenable to the influence of others. The few homes which now exist for the care of the feeble minded show that by the exercise of much patience and under careful supervision the inmates can do satisfactory work, lead happy lives, and make the homes at least partly self supporting. A larger number of permanent homes with powers of forcible detention in suitable cases seems the only satisfactory method of dealing with the subject—of rescuing these unfortunates from the wretchedness to which so many are condemned and arresting the transmission of their defects to unborn generations It is a subject which will have to be dealt with by the State before much progress can be made.

I am, Sirs, yours faithfully,
F. MAY DICKINSON BERRY, M.D, B S. Lond.,
Assistant Medical Officer to the School Board for London.
Wimpole-street, W., May 27th, 1902.

WHAT IS A "CURE"?

To the Editors of THE LANCET.

SIRS,—I read the leading article "What is a Cure?" in THE LANCET of May 24th (p. 1478) with some interest, especially the passage relating to the scepticism that now obtains amongst a large and growing number of medical men as to whether our therapeutic measures do even help to bring about a cure. When I read on and came to the illustrations you gave of the fruits of the scientific study of medicine my interest deepened because you gave expression to the state of mind that is common not only among medical men but also among laymen. I do not, of course, deny that antitoxin in diphtheria and thyroid gland for myxœdema are brilliant triumphs of scientific discovery, but if these specific treatments are the only things that medicine can boast and the only future she awaits is for every other disease to have its like specific remedy, then where will be the need of the physician? The patient would in these enlightened days merely have to get his complaint diagnosed before repairing to a penny-in-the-slot machine to obtain his specific remedy and *c'est tout.* Indeed, in these days of tabloids and shallowness, we are a step or two in that direction already.

Now, Sirs, I contend that although without doubt our forefathers in medicine put too much faith in drugs, we are, as usual, going to the other extreme and are putting too little faith in them. Our want of faith is born frequently of as great ignorance as their belief and certainly of greater shallowness of thought.

The true physician in these days when surgery is being lauded to the skies—its successes how apparent, its failures how numerous and awful and frequently tragical, in private practice especially—is becoming either a *rara avis* or at any rate a timid one, for his voice is seldom "heard in the land" in vindication of his art. I contend that the skill of the physician in regard to treatment is seen not in giving such preparations as that of thyroid extract for myxœdema but in the skill which he displays in treating each case of departure from the normal rightly termed disease as a separate study and problem to be solved, by his drugs (perhaps using them as a sort of "liberating energy") calling into play the latent powers of nature or checking her too boisterous manifestations, it may be by displaying a "masterly inactivity" at certain stages and at the right time giving a suitable drug or drugs in the right combination in the right dose to assist, to coax, or to stimulate the vis medicatrix naturæ to lead on to health. There is no doubt that the commercial spirit, the rush of private practice together with low fees, club work with the resulting bodily exercise taking the place of mental, is driving many a practitioner into becoming anything but a thoughtful physician. In conclusion, if we had no other drugs than those handed down to us by our forefathers I do not think I shall be alone in saying that by them we could obtain (even as we are obtaining) glorious triumphs over disease. But if any man, either as a result of training or of mental gift, have not what has been called the "Mens Medica" then drugs and medical therapeutic remedies generally will be in his hands like the most beautiful colours in the hands of him who knows not how to paint.

I am, Sirs, yours faithfully,
May 30th, 1902. A. W. FULLER, M.B. Edin., &c.

THE CASE OF DR. W. T. LAW.

To the Editors of THE LANCET.

SIRS,—In this busy life so many things are constantly occurring, absorbing our attention, that we sometimes fail to appreciate the gravity of a charge which, according to a righteous judge and jury, ought not to have been brought against one of ourselves. Such is the case of Dr. W. T. Law who had to undergo a painful trial, being sued for £5000 by a former patient. Dr. Theodore Williams in his excellent speech at the King's Hall on May 9th said he never knew a patient who was suffering from spasmodic asthma who had so much done for her as was done by Dr. Law.

THE LANCET says in its issue of May 3rd: "Owing to the poverty of the plaintiff Dr. Law is saddled with the payment of heavy costs. At any moment anyone of us may find himself in a like position and we therefore hope that not only will the leaders of the medical profession subscribe their guineas but that the rank and file thereof will send their shillings. Sympathy is a great thing but, as the Apostle James remarked, 'If a brother or sister be naked, and destitute of daily food, and one of you say unto them, Depart in peace, be ye warmed and filled; notwithstanding ye give them not those things which are needful to the body; what doth it profit?' So let us show our sympathy in a practical way. And in particular we hope that the subscriptions will flow into the fund from the profession at large, for the matter is one of vital importance to them and they should recognise it."

Many of Dr. Law's professional brethren have shown their sympathy for him in a practical manner, for which he is extremely grateful. Some who have given to the fund already have promised to give more if others will not lend a helping hand. Some have been good enough to leave to me the amount that they should give. Several who have already given would have gladly given more if they were asked to do so. Others have written expressing the hope that more than the actual amount required will be forthcoming as a compensation for the indignity, worry, and loss of health which such a trial necessarily entails. In a case like this, affecting the honour, the prestige, and the liberty of the profession, it is desirable that many should show their interest in this unusual and exceptional case. Fortunately, Dr. Law is rich in the possession of sincere friendship, which many really wealthy men do not possess. At the painful trial his friends came to the rescue to give evidence in his favour. The grand service of Dr. Theodore Williams is well known and the testimony of

Sir Richard Douglas Powell, who although suffering from an attack of influenza came willingly to court, was no less valuable. If such sympathy can be displayed, ought not many to carry out the good advice of THE LANCET and join others who have been, and are, doing their best for one who did his best for his patient?

I leave the matter in the hands of my brethren, thanking the medical profession for what it has already done, and especially the medical press, ever jealous of maintaining its reputation of being a noble and generous profession.

I am, Sirs, yours faithfully
RICHARD PARAMORE.

2, Gordon-square, W C., June 3rd, 1902.

PS.—I inclose a list of additional *subscriptions*.[1] Postal orders and cheques should be made payable to the Law Fund and crossed London and County Bank, Holborn, W C

THE SIMULATION OF ABDOMINAL BY THORACIC INFLAMMATION

To the Editors of THE LANCET

SIRS,—The reference to the paper of Mr H. L Barnard and Dr M H Richardson on "The Simulation of Abdominal by Thoracic Inflammation" in THE LANCET of May 17th, p 1414, reminds me of a case under my care some few years ago I was called late in the evening to a man said to be suffering from acute abdominal pain. I was told by the wife that the pain had come on shortly after a light meal partaken of by her husband on returning from work, and both she and the patient had confidently diagnosed the case as one of poisoning by the margarine eaten at this meal On examination I found the abdomen somewhat rigid and apparently markedly tender without any specially tender spots Vomiting had occurred without any great relief The temperature was normal and the pulse and respiration, though both increased, were not, I think, very significant of the condition afterwards diagnosed. I do not now remember exactly what increase they showed or what was the ratio but I remember I proceeded to examine the chest rather to satisfy myself that I was not missing anything than because I expected to find the main cause of trouble there. The patient, who was evidently suffering acute pain—all, or nearly all, referred to the abdomen—considered this chest examination a work of supererogation which he was irritably inclined to resent. I was very glad, however, that I made it, as I found fairly well marked signs of pneumothorax on the right side, which helped to clear up what promised to be a difficult and misleading case This patient, I may add recovered after a somewhat protracted illness, and I have no reason to suppose that there was any abdominal disease to account for the severe pain referred to that region This condition of "referred pain" is a possibility which must be constantly borne in mind if one would avoid mistakes Perhaps the most familiar instance of it is that of pain in the knee-joint due to hip-joint disease, but many other examples could be given which are frequently met with by every practitioner

I am Sirs, yours faithfully,
R WHITTINGTON

SOUTH AFRICAN CIVIL SURGEONS' DINNER

To the Editors of THE LANCET

SIRS,—We shall be much obliged if you will allow us the use of your columns to request all civilian medical men who have served during the recent war in South Africa to do their best to be present at the above dinner at the Hotel Cecil, next Monday, at 7 30 P M Sir F Treves will be in the chair, and the Director-General and Deputy Director-General of the Army Medical Service will be the principal guests. There will be two toasts, those of "The King" and of "The Imperial Forces," so as to leave ample time for the main object of the evening—the renewal of South African friendships and memories. Tickets price 10*s* 6*d* each, may be purchased at the door, but we shall be glad to be informed beforehand of intending diners Medals and orders may be worn.—We are, Sirs yours faithfully,

FRANCIS E. FREMANTLE, } Honorary
C. GORDON WATSON, } Secretaries.

The College, St. Bartholomew's Hospital, E.C., June 4th, 1902.

THE ROYAL NAVY MEDICAL SERVICE AND THE ROYAL ARMY MEDICAL CORPS A COMPARATIVE VIEW

To the Editors of THE LANCET

SIRS,—I have read with much interest your leading article and the new regulations for the Naval Medical Service, both published in THE LANCET of April 26th As the parent of a prospective candidate for one of the services just about qualifying, the following points of difference between the new Army Warrant for the Royal Army *Medical Corps* and the new naval regulations struck me as being worthy of careful consideration.

1. *Article 349*, new Army Warrant, seconds newly-entered officers while holding appointment of house surgeon at a civil hospital and guarantees them the time so spent shall count towards promotion, pension &c. The new naval regulations say, *if* a surgeon has held the appointment of house surgeon before entry he *may* receive earlier promotion to staff surgeon.

2. *Article 352, Army*, gives officers the opportunity of gaining from three to 18 months' earlier promotion on passing their promotion examination with distinction *Navy* No such provision

3. *Articles 356 and 366, Army* Brevet promotion and brevet pay in addition to ordinary pay for a captain in the Royal Army Medical Corps. *Navy* No similar provision.

4 *Article 368, Army* Charge-pay for officers of whatever rank in charge of beds according to numbers *Navy* Charge-pay for inspector generals only Three out of a total of some 500 of all ranks

5. Officers of the Royal Army Medical Corps may be granted full pay sick leave up to one year with possibility of extension. *Navy* Limited to three months, after which half pay

6. Officers of the Royal Army Medical Corps qualifying as specialists to receive 2*s*. 6*d* a day in addition to ordinary pay *Navy* No such provision

7 Staff surgeons employed in London to receive hospital allowances of £53 in addition to lodging allowances of £50 total £103 per annum Major in the Royal Army Medical Corps of equivalent rank is to receive allowances totalling to £160 per annum.

Does the Admiralty really think that with all these substantial differences in favour of the Royal Army Medical Corps candidates of ability will ever be likely to enter the navy as surgeons so long as they can be received into the Royal Army Medical Corps? I notice that the Admiralty is now advertising 30 commissions as surgeons for competition in June. Let it equate the conditions of its service to those of the Royal Army Medical Corps if it really desires candidates to respond

I am, Sirs, yours faithfully,
PARENT

May 17th 1902.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Plague Epidemic —Disgraceful State of the City of Ahmedabad —The Religious Census of India.—The Prevention of Tuberculous Disease

THE plague epidemic throughout India continues to show signs of declining The total mortality for this week is 16,748 against 17,302 for the previous seven days For the corresponding week of last year the deaths from plague amounted to only 3208. The figures for this week are smaller everywhere but the epidemic may be said to be raging fiercely at Karachi, Bombay and Calcutta, and more especially throughout the affected districts of the Punjab. The figures are Bombay city 488 deaths, Bombay districts 930, Karachi city, 106 Madras Presidency, 11, Calcutta 441, Bengal districts 473, United Provinces 718, the Punjab 12,334 Central Provinces, 98 Hyderabad State 28, Kashmir, 108, and Berar, 18.

I have frequently pointed out the incompetency of certain municipalities in India for the sanitary administration of their towns. The city of Ahmedabad has become so bad that the Commissioner of the district has had to threaten to move the Government to interfere. The mortality has been increasing and is now 77 per 1000 without any epidemic to account for it. The city is overcrowded and dirty, and the paths and roadways are very badly kept up. Accumulations of refuse abound, there is a want of surface drainage, the roads are very irregularly watered, and a great waste of pipe-water goes on. There is an open violation of by-laws regarding dangerous and offensive trades. Encroachments are permitted on the public roads, insanitary dwellings are very numerous, and nuisances abound. The registration of births and deaths is very defective and the taxes are remissly collected. This is a sufficiently strong indictment against the corporation and it is to be hoped that Government will take the administration of the city out of its hands.

---

[1] This list will be found on p. 1656.—ED L.

It will probably interest your readers to hear the result of the census so far as the numerical distribution of the chief religions in India is concerned: Hindus, 207,075,277; Sikhs, 2,195,268; Jains, 1,334,148; Buddhists, 9,476,450; Parsees, 94,190; Mahomedans, 62,458,061; Christians, 2,923,241; Jews, 18,228.

The Bombay Municipality some time ago appointed a committee to frame measures for the prevention of tuberculous disease. The following is the report of this committee:—

> The committee have carefully studied the resolutions passed at the general meeting of the British Congress on Tuberculosis on July 27th, 1901, and have considered the subject with special reference to local conditions and to the habits and prejudices of the varied populations of this city. With the conclusions of the Congress, as embodied in their resolutions, this committee are in full accord, and although it would not be possible in this country to give effect to all their recommendations, yet it seems to this committee that it is absolutely necessary to do something in the direction indicated by them to combat so fell a disease as phthisis which is year after year so increasingly conspicuous in the mortality returns of the city. In consultation with the health officer the committee have framed the following suggestions for the prevention of the disease, which they think are of a practical nature and not unsuited to the circumstances prevailing in the city.—
>
> 1. Voluntary notification by medical men to the health officer of every case of tuberculosis coming to their knowledge.
> 2. Facilities to be given for a bacteriological examination of sputum sent by medical men to a health officer to ascertain whether tubercle bacilli are present.
> 3. Instructions to be given how to disinfect a room in which a case of tuberculosis has occurred and died.
> 4. Instructions to be given how to disinfect sputum and to prevent the bacilli spreading the disease
> 5. Disinfection and lime-washing of every infected house at municipal expense, where necessary in the opinion of the health officer, and systematic lime-washing of every common lodging-house twice a year at owner's expense
> 6. Printed instructions in English and the vernaculars to the people, and instructions by male and female visitors as to the precautions necessary to prevent the spread of disease and notices posted as to spitting.
> 7. Prevention of overcrowding in houses, factories, and workshops.
> 8. Ventilation of houses, printing-offices, and workshops, and removal of dust from wool- and cotton cleaning godowns and all trade processes causing pollution of air liable to affect the lungs and predispose to infection.
> 9. Inspection of milk- and meat-supplies and analysis of milk.
>
> The committee are of opinion that at present action on the lines of these suggestions would be sufficient. The effect of these should be carefully watched and further measures can be decided on as they seem necessary.
>
> It will be noticed that suggestion No. 1 is for voluntary, and not compulsory, notification of tuberculosis by medical men.
>
> Suggestion No. 2 will involve expenditure, but the committee think it will be very useful and necessary expenditure.
>
> With regard to suggestions Nos. 3, 4, and 5 disinfection and lime-washing may, so far as possible, be left to the people themselves, not so much on the ground of expense as on the ground of giving no cause for irritation, but rather than that it should not be done at all it may even be done at municipal expense. A discretion must therefore be given to the health officer to do it at municipal expense and by municipal agency whenever he thinks it necessary.
>
> As to suggestion No. 6, the provision of sanatoria will be more a matter for the munificence of wealthy citizens whose attention should be drawn to the great good which institutions of the kind are calculated to do to the suffering poor. The committee hope that the public press, both English and vernacular, will help to keep the matter constantly before the public.
>
> Continuous and persistent action on the lines indicated in the above suggestions will, the committee think, to some extent contribute to check the growing ravages of this disease, which appears to have taken so firm a hold of the many densely crowded sections of this city, such as Second Nagpada, Umerkhari, Chakla, Kamatipura, Kharo Talao, Mandvi, and Bhuleshwar. The committee, therefore, beg to recommend that the Commissioner be asked to take the necessary steps for giving effect to these suggestions, submitting proposals to the corporation in respect of such of them as involve additional expenditure.
>
> D. E. Wacha. Bhalchandra Krishna.
> H. P Dimmock. K. E. Dadachanji.
> May 9th. N. N. Kathak. D. A. D'Monte.

The Plague Epidemic throughout India.

There is again this week a satisfactory decline in the mortality from plague throughout India. The decline is general but in Karachi the disease is raging with great intensity. There were 11,612 deaths in India from plague for the week ending May 10th, as against 15,748 for the previous seven days. For the corresponding week of 1901 there were only 2592 deaths. The chief districts affected are Bombay city with 391 deaths; Bombay districts, 583 deaths; Karachi, 122; Madras Presidency, 13; Calcutta, 280; Bengal districts, 337; United Provinces, 417; the Punjab, 9192; Mysore State, 70; and Kashmir, 212. In the two cities of Calcutta and Bombay the outbreaks are now rapidly declining. In neither city, however, has the outbreak attained the same intensity as did those of last year. In Calcutta the outbreak has been much more prolonged. There has been no further development in Eastern Bengal. It is satisfactory to find that the mortality in Bombay apart from plague is coming down to its normal level.

May 15th.

MANCHESTER.

(From our own Correspondent.)

Manchester Royal Infirmary.

It appears as if the board of management of the Manchester Royal Infirmary were committed to rebuilding on the present site. At the meeting of the board on May 26th the chairman, Sir J. Forbes Adam, said that it would be remembered with regard to the rebuilding of the infirmary that the plans were passed subject to certain alterations and that they were referred back to be dealt with by the sub-committee. The sub-committee had been working with the architects and the plans, finally changed and with all the suggestions carried out, would be ready on June 17th. The Coronation festivities would cause some delay and it would probably be the third week of July before the trustees' meeting would be held. The trustees will probably be guided by the board as to the decision which they will come to. The plans are not yet made public and they cannot therefore be criticised, but the site is there for anyone to see. It comprises in all 19,580 square yards, or 22 yards more than four acres. On this restricted plot of ground buildings are to be erected giving superficial area and cubic space sufficient to accommodate 457 patients. In addition to the patients there is at the present time a household of more than 140 persons, and when the number of patients is nearly doubled the staff of officers, nurses, and servants must be largely increased, so that probably 700 people will be lodged in the infirmary. This is a high number per acre. The pungent winter fogs cause much suffering and injury to patients with diseases affecting respiration and discomfort to others. A little further from the centre, though there may be fog, it is less charged with acrid, irritating particles and gases. Immediately surrounded as the present wards are with streets and noisy traffic all day and a good part of the night there is no quiet freedom from jarring sounds.

City Electrical Generating Station.

A new generating station is in course of construction in Manchester. It is situated in Bradford, one of the industrial suburbs, and the first completed portion was opened by the Lord Mayor on May 27th. The site has an area of 8½ acres—considerably more than twice that of the infirmary site—and when finished the station will be one of the largest of its kind in the world, providing accommodation for machinery of 70,000 horse power. The cost is expected to be at least £1,000,000. In accordance, therefore, with a law that seems almost to be universal it will probably be half as much again. The first municipal electrical works in Manchester were established in 1893 with machinery for generating 3000 horse power.

Small-pox.

Many cases of small-pox have recently been notified to the medical officer of health of Derbyshire. A navvy, lately working at Bamford and now living in Chapel-en-le-Frith, has been attacked, and it is feared that he may have communicated the disease to some members of the great colony of navvies now engaged on the preliminary work in connexion with the Derwent Valley Waterworks. In 1893 the authorities had an immense amount of trouble through small-pox spreading among the navvies employed on the Dore and Chinley Railway Works when Chapel-en-le-Frith was the seat of the epidemic. There are said to be 10 cases at Ilkeston, two at Ripley, and several at Chesterfield. Two cases at Derby are traceable to tramps, in regard to whom the authorities just now have to be especially vigilant. Manchester has fortunately been free from small pox since the present epidemic began.

Manchester Sewage

Manchester has so long suffered from the sins of its forbears as regards its sewage and from the reproaches of the Mersey and Irwell Joint Committee that it is a consolation to receive the slightest commendation and encouragement. At the meeting of the committee on June 2nd Mr Tatton, the chief inspector, reported that six acres of bacteria beds which were dealing with about 2,000,000 gallons of sewage daily had been completed and that a beginning had been made with 20 acres of beds to be similarly constructed. It was expected that by the end of the summer there would be temporary provision for the treatment of another 4,000,000 gallons by means of 13 acres of filters which would ultimately serve as storm water filters Mr Tatton thought that fair progress had been made. The corporation has applied to the Local Government Board for powers to borrow nearly £400,000 to cover the cost of works at Flixton. It is to be granted an extension of time again for six months.

Prosecutions of Butter-dealers

A wholesale butter dealer in Manchester had to pay a fine of £20 the other day for selling the cheapest form of margarine as "creamery butter" It was certified to contain 80 per cent. of fat which was not butter and about 11 per cent. of water In another case a dealer was fined 5s and costs for selling butter which was certified to contain 20 per cent. of water

The late R. Charnley Smith, M D St And., D Sc Edin., J P

Dr R. Charnley Smith died on May 30th, in his sixty eighth year For many years he had lived and worked in an industrial neighbourhood in Manchester, he was devoted to his profession but yet found time not only to cultivate his classical and literary tastes but to give his services to Manchester for several years as a member of the school board, a member of the city council, and a justice of the peace. The chairman of the magistrates on June 2nd paid a warm tribute to his memory

June 3rd

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

University of Wales.

THE three constituent colleges of the University of Wales are in Aberystwith, Bangor, and Cardiff, and the offices of the registrar are at present at Aberystwith, the court of the University hitherto having been unable to decide where they should be permanently located, some members of the court advocating the claims of one collegiate town and others those of the remaining while a few members were of opinion that the offices should not be in a collegiate town at all but in some part of Wales centrally situated and readily accessible. An almost unanimous decision was arrived at on May 30th to erect suitable buildings at Cardiff, the corporation of which town offered a free site and a contribution of £8000 towards the building fund. The proposed site is in Cathays Park—an estate situated in the very centre of the town which has been acquired by the corporation from the Marquis of Bute and is to be used exclusively for public buildings. A new town hall and law courts are now being erected and other portions of the park are being rapidly allotted.—The annual extra-collegiate meeting of the University of Wales was held at Shrewsbury on May 30th under the presidency of the Deputy Chancellor (Dr Isambard Owen). It was reported that the newly appointed Chancellor the Prince of Wales, had sent a donation of £100 towards the Fellowship fund. Dr Isambard Owen was unanimously re-elected senior deputy chancellor and Sir Lewis Morris junior deputy chancellor

Cardiff Medical Society

The annual meeting of the Cardiff Medical Society was held on May 29th when Dr Richard Prichard, medical officer of health of the Llandaff and Dinas Powis Rural District Council, was elected president for the next session. Dr C. Theodore Williams, consulting physician to the Brompton Consumption Hospital, subsequently gave an address upon the Hygienic Treatment of Pulmonary Tuberculosis Dr Williams described with the aid of lantern slides and photographs various sanatoriums which he had visited in Germany and elsewhere, with especial reference to their situation, surroundings, arrangements for open-air treatment, &c. He advocated moderately heavy feeding but stopping short of the vomiting point, moderate and graduated exercise in certain cases, and all possible time spent in the open air, especially in the prone position but with the head and thorax sufficiently raised to permit of ready expectoration. He also laid great stress upon the necessity for having a strong man at the head of a sanatorium with sufficient influence and authority to enable him to see that his instructions were strictly carried out. In view of the keen interest which is being taken in the subject in South Wales at the present time Dr Williams's lecture was most opportune and his account of the great good accomplished at the sanatoriums which he described ought to hasten on the erection of the proposed institution for Glamorganshire and Monmouthshire In the evening the members of the society and their friends dined together

Bristol Port Sanitary Authority Report of the Medical Officers of Health

Quite nine-tenths of the annual report of Dr D S. Davies and Mr J C. Heaven addressed to the Bristol Port Sanitary Authority is concerned with the question of the introduction of plague by rats. The key of plague prevention in their opinion, is the extermination of rats, and although supervision of infected persons and articles must necessarily be maintained on ordinary lines of intelligent control they consider that there is not one tithe of the danger involved in the arrival of a plague patient at a non infected port that there is in the arrival of a vessel with infected rats in the hold It is recommended that all merchant vessels, and especially those engaged in the grain trade, should be periodically fumigated to destroy rats without introducing the question of infected ports at all. If the vessels arrived practically free from rats the risk of infection would be very materially lessened. It appears that in Hamburg for some years past rats have been destroyed on all incoming ships and after discharge any ship giving rise to suspicion is fumigated with sulphur by the authorities. The report gives a brief account of the outbreaks of plague at Glasgow in 1900 and in Liverpool, Hull, and Cardiff in the following year, and in more detail the experience of Bristol in January, 1901, when six dead rats, subsequently found to be infected with plague, were found on a ship 15 days out from Smyrna. A portion of the cargo of grain had already been discharged before the ship was certified as infected when the holds were twice subjected to sulphur fumigation and 226 rats were destroyed The 117 men known to have had any connexion with the unloading of the vessel were kept under observation for 14 days from the last exposure to infection, two assistant medical officers being appointed to carry out this duty No case of human plague resulted. Incorporated in the pages of the report is the resolution passed by the Associated Chambers of Commerce at the meeting held at Nottingham in 1901 and which contained a recommendation that the captains of vessels loaded at plague-infected ports should be ordered to destroy rats on board ship before loading cargo and should take precautions to prevent rats getting on board during the time that cargo is being loaded.

Vaccination Questions.

At the meeting of the Andover Board of Guardians held on May 23rd a proposal was made to publish in the list of paupers the names of those persons who had been re-vaccinated at the expense of the ratepayers. One of the guardians however stated that he had recently inquired from the Local Government Board upon the matter and was informed that this would be an illegal act, that the guardians would throw themselves open to action for injunctions and damages and would be surcharged the cost of publishing the lists The Local Government Board also stated that persons who accepted free vaccination could not be classed as having received outdoor relief.—At the meeting of the Honiton (Devon) Board of Guardians held on May 24th it was stated that the public vaccinator for Sidmouth had recently vaccinated two children belonging to a tramp at his surgery instead of at the residence of the parent, which was a common lodging house The auditors of the Local Government Board had disallowed the fees The public vaccinator stated that the reason he performed the operation where he did was for cleanliness. The guardians decided to appeal against the surcharge.—At the meeting of the Okehampton (Devon) Board of Guardians held on May 24th it was reported that several residents whose names were mentioned at the previous meeting had sent the fees for revaccination. The guardians resolved that the names of all who had been revaccinated at the cost of the ratepayers should be read at their next meeting.—At a meeting of the Gower (Glamorganshire) Board of Guardians held on May 27th the chairman said that the medical officers in some cases vaccinated their own children at the cost of the ratepayers. The guardians decided that the list of persons who had been revaccinated should be scrutinised by a committee. —At a meeting of the St. Thomas's Board of Guardians (Exeter) held on May 30th it was decided to submit several questions for the consideration of the Local Government Board. Amongst these the guardians desired to know if a public vaccinator had a right to refuse to accept payment from persons revaccinated; when several hundreds of patients in lunatic asylums were revaccinated whether the public vaccinator was justified in refusing to accept a less sum than the full fee for revaccination at the home of the patient; and whether the full fee was payable in cases where the public vaccinator revaccinated several people living in one house, including the servants. It was mentioned that at Exmouth, out of 410 cases of revaccination 407 persons were operated upon at their own homes; and at Budleigh Salterton, out of 109 cases only nine persons had been revaccinated at the surgery.

June 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE annual report and financial statement of the Royal College of Surgeons in Ireland for the year ending April 5th, 1902, was submitted to a meeting of the Fellows held on May 31st. The President, Mr. Thomas Myles, in explaining the chief features of the account made some interesting remarks. The prospects of the College from a money point of view had changed for the better, the burden of debt caused by the amalgamation scheme having now completely disappeared. The Council had, moreover, during the past year made many purchases for the library and commenced the development of the museum by a special grant to the curator. Since the last report many of the Fellows and Licentiates have received honours and distinctions for their services in the South African war. Two had received the honour of C.B., five that of C.M.G., one that of C.I.E., three the D.S.O., and one the Victoria Cross.—The annual meeting for the election of the President and Council took place on June 2nd with the following result: Mr. Lambert Hepenstal Ormsby was elected President in succession to Mr. Thomas Myles, whose term of office has terminated, Mr. Arthur Chance was elected Vice-President, while a quite unusual number of changes took place in the *personnel* of the council. Mr. Myles has resumed his place on it and no less than five new members have been elected: Mr. Thomas Donnelly, Mr. F. T. Newell, Mr. J. D. McFeely, Mr. William Taylor, and Mr. H. W. Oulton.

The Irish Medical Association.

The annual general meeting of the Irish Medical Association was held on June 3rd in the hall of the Royal College of Surgeons, Stephen's-green. Dr. F. P. McLoughlin of Strangford, Vice-President, occupied the chair at the commencement of the proceedings, giving place later to Dr. J. Cranny, the newly elected President, who delivered an address.

Royal Medical Benevolent Fund Society of Ireland.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held on June 2nd in the hall of the Royal College of Physicians, Dr. Walter G. Smith being in the chair. Sir J. W. Moore read the annual report, the adoption of which was moved by Sir Philip Smyly and seconded by Sir Thornley Stoker. It appeared that £1330 had been given away in grants, while the receipts in subscriptions during the year only amounted to £450.

College of Science in Dublin.

On May 28th in a discussion in the House of Commons on the second reading of the Public Offices (Dublin) Bill as to whether the new College of Science should be built on the north or south side of the city of Dublin, a very strong protest was made by the north of Ireland members against the selection by the Government of the city of Dublin in which to build a college of science. Their view was that to spend £250,000 for a college in a place where, according to them, it would be little used would be a mistake. Such a college taught technical subjects and matters connected with manufactures of all sorts of articles in Ireland, and according to Mr. G. W. Wolff, M.P., one of the members for Belfast, should be placed in Belfast. At the Royal Commission on Technical Education in 1886 Dr. W. K. Sullivan, President of Queen's College, Cork, said: "The people of Dublin who have been crying out for technical education lately do not seem to know that they have had in their midst for the last 20 years one of the most complete polytechnic schools in Europe. If it has not done so much good as it might have done it is the fault of the people of Dublin." The Government is wise in trying to make the scheme of technical education in Ireland complete by establishing a college of science, but strong arguments are forthcoming for locating such a college where technical instruction is most in demand and where manufacturing industry is greatest. The county council of the city of Belfast has passed a resolution that facilities for all grades of technical instruction should be furnished for Belfast on a scale at least equal to that provided for Dublin.

Small-pox in Belfast.

I regret to report an increase in the number of small-pox cases in Belfast. The original cases were taken to the Union Hospital and it is said that 16 cases have occurred there and four in all have been admitted from the city. It is contrary to all modern ideas that a place like the Union Hospital, in the heart of the city and with the adjacent workhouse close at hand, should be the only hospital for cases of a disease like small-pox, which needs such thorough isolation and constant supervision. The Public Health Committee has arranged to erect a temporary hospital at Purdysburn at the cost of £1600 (it should have been done long ago) and it has appointed a sub-committee to take into consideration the erection of additional huts if necessary. It has also arranged to utilise the hospital at the Twin Islands for the contacts, where these people are to be sent overnight, bathed, disinfected, and vaccinated, and sent out, it is hoped, freed from infection. It would be wiser to keep them for a fortnight until the period of incubation had passed.

Belfast Union Workhouse Medical Expenditure.

During the week ended May 29th Dr. J. Smyth, medical inspector of the Local Government Board, has been conducting an inquiry in the board-room of the Belfast Union Workhouse relative to the expenditure on medicines and medical and surgical appliances in the Belfast workhouse and the several dispensary districts of the Belfast Union during the half year ended March 31st, 1902. A variety of evidence has been put forward and it will be some time before the result is known, but on the last day of the inquiry the inspector stated that he had taken an opportunity of seeing the Nurses' Home and had been surprised to find that one item, sugar, supplied to the nurses had been supplied in such enormous quantity that the supply in the week before had not been consumed and that two stones remained, and that the whole of the supply for the week which was passed at the date of his visit was still untouched and that pile after pile of articles unconsumed remained heaped upon the shelves. This he regarded as a serious question as regards the training of nurses in the Belfast Workhouse, as the nurses see in their own home an object lesson of what is undoubtedly extravagance. What he saw, the inspector stated, did not impress him either as good or economical administration. The head of the nurses' home said the work expected from her was excessive, as when she came first there were only 40 nurses, now there are 91. The inspector having spoken of the help which he had received from the clerk of the union, the master of the workhouse, and the medical officers, said the decision as based on the evidence would rest with the Local Government Board.

Cork Medical and Surgical Society.

The annual meeting of this society was held on May 28th. There was a very large attendance of members. The following officers were elected for the session 1902–03:—President, Dr. P. T. O'Sullivan; vice-president, Dr. J. Cotter; retiring president, Dr T G Atkins, honorary secretary, Dr. D J O'Connor; honorary treasurer, Dr P J O'Brien, council, Dr W A Cummins, Dr O Y Pearson, Dr N H Hobart, Dr T B. Moriarty, Dr J Giusani, Mr E. Murphy, and Dr H R. Townsend The financial statement showed a large balance to the credit of the society, the number of members being the largest on record

June 3rd.

PARIS

(FROM OUR OWN CORRESPONDENT)

Chloroform in Heart Disease

AT the meeting of the Academy of Medicine held on May 20th M. Huchard summed up the important discussion which he has been so ably conducting It has led to the conclusion that administration of chloroform is admissible in cases of senile heart and also when the heart is the subject of valvular lesions. Cardiac intermittence and syncope during the administration of chloroform are not, in most instances, the effect of cardiac disease, even aortic insufficiency is not a cause of syncope. Among 100 deaths under chloroform there are not 10 in which the heart is at fault. Consequently cardiac disease, short of being in the stage of asystole, is not a contra indication to the use of chloroform. Purity of the chloroform and skill and attention on the part of the anæsthetist have much to do with the obtaining of a successful result and the importance of the part taken by the administrator has induced M Huchard to ask for the appointment of special anæsthetists. Extreme irritability in the chloroformed patient might be the means of giving rise to reflex shock and the method of administration selected is of very great consequence. M. Gosselin caused chloroform to be inhaled in small doses mixed with air M. Richelot commenced the inhalation with an inhalation of bromide of ethyl. M. Laborde recommended the preliminary injection of morphine, atropine, and sparteine, or painting the mucous membrane of the upper respiratory tract with cocaine, morphine diminished nervous excitability and the patient became unconscious more easily, but atropine might appear to be dangerous. The superiority of ether over chloroform was not altogether proved. At all events ether was absolutely contra indicated in pulmonary affections. Sédillot's aphorism might, in fact, be modified to the effect that the careful administration of chloroform, with attentive watching of the effects produced, was not dangerous for a patient who had been properly prepared. M Laborde expressed the opinion that atropine was an important constituent in the prescription which he had given for the subcutaneous injections designed to prevent chloroform accidents,[1] for atropine was an antidote to morphine and had an influence on the motor action of the pneumogastric. M Le Dentu, on the other hand, was apprehensive as to the possible effects of preventive injections in connexion with surgical shock, especially in operations of long duration. M. Championnière said that on trying the system recommended by M Laborde he had been caused so much anxiety by the respiratory syncope which occurred that he would never repeat the attempt. To this M. Laborde replied that these trials had been made with solutions containing atropine in such a small quantity that its effects were inappreciable.

Treatment of Small-pox

At the same meeting of the Academy of Medicine M. Landouzy read for M. Barbary a communication in which the author stated that he had treated eight cases of undoubted small pox by isolation in a room in which only red light was permitted and by the adoption of the following aseptic and antiseptic measures. In the morning, in the course of the day, and in the evening the whole body was washed with a solution of corrosive sublimate of the strength of 1 in 200, a warm solution of the strength of 1 in 4000 being also vaporised twice a day over the face The eyes, nose and ears were also washed gargles were used, and the mouth received attention. Morning and evening, a considerable time after the vaporisation the face and other parts on which the eruption existed were painted with a mixture consisting of five grammes of salicylate of soda, 10 grammes of cherry laurel water, and 10 grammes of alcohol. Copious enemata of a boiled watery solution of boric acid were given every morning The medicines taken internally were a teaspoonful of *sirop phéniqué* twice a day and a *cachet* of 20 centigrammes of salol and 25 centigrammes of hydrobromate of quinine twice a day when the patient's temperature seemed to require it. Milk was given every two hours alternately with coffee or eau de Vichy (Célestins). Under this system of treatment adopted by M. Barbary the eight patients recovered rapidly, their temperature fell at an early stage, there was no suppuration, there were no complications, the disease ran a very rapid course, and when desquamation was completed there was no marking of the face.

Bilateral Ureteral Catheter

At the same meeting of the Academy of Medicine M. Guyon presented, on behalf of M. Cathelin, a graduated bilateral ureteral catheter (*diviseur vésical*) by means of which the urine from each kidney could be collected separately in the bladder

Centenary of the Internat

The French hospital appointments which correspond approximately with those of house physician and house surgeon in England were originally created on Feb 25th, 1802, and are known collectively as the Internat des Hôpitaux, those who perform the duties being called *internes*. Now that the *internat* has completed the hundredth year of its existence an opportunity for holding centenary celebrations presented itself, but the *fêtes* in question did not take place until May 24th and 25th, dates considerably later than the actual anniversary It was at first intended that they should be held in April, and the committee of management had the agreeable expectation that the President of the Republic would take the chair, but the appointed date unfortunately coincided with a general election to the Chamber of Deputies, a period during which the Chief of the State and the Ministers make it a rule not to appear in public in an official capacity The date was therefore altered to May 24th and 25th, but once more the hopes of the committee were disappointed for M Loubet was then in Russia. M Waldeck Rousseau consequently presided at the *fêtes* The proceedings of the first day opened with a formal meeting in the great hall of the Trocadéro where official speeches were delivered. At night there was a grand banquet attended by 700 *internes* or former *internes*, many of whom had come specially to Paris from the country and from abroad, the entertainment winding up with a musical evening On May 25th, at 10 A M, a mass in memory of the *internes* who had met their death in the performance of their duty was celebrated in the Cathedral of Notre Dame by the Cardinal Archbishop of Paris in person. A small monument erected in the court of the Hôtel Dieu in memory of these victims to duty was unveiled at 2 P M on the same day The monument, which had been executed by the chisel of the sculptor Denis Puech consists of a bas-relief of moderate size placed against the wall of a corridor and represents an *interne* engaged in performing tracheotomy on a child suffering from diphtheria whose head is supported by a sister of charity Notwithstanding the talent of the artist the general effect of the design is lifeless, and is suggestive not so much as a work of art, as of an illustration intended for a surgical text book. In the evening there was a gala performance at the Opéra Comique there was a gala performance at the Opéra Comique Theatre in aid of the benevolent fund maintained by the *internes* The cost of these celebrations was borne by the former *internes* who opened a subscription list for the purpose and were presented with memorials of the proceedings in the form of a silver medal and a book recording deeds of heroism and devotion to duty performed by *internes* The general idea underlying these anniversary *fêtes* was very touching and it is certain that the whole medical profession would have entered heartily into the spirit of them if the organisers had not rapidly lost sight of the original intention and allowed the proceedings to degenerate into a public glorification of what might be called the caste of the medical men who had in their time been *internes* They are very proud of the title "*ancien interne*," and in the competition engendered by the overcrowding of the medical profession in the present day they try to flourish it before the general public in the hope of obtaining more recognition than their fellow practitioners. The plain truth is that the *interne* who exists only in France is neither more nor less than a student admitted to act as assistant to the physician or surgeon in charge of a hospital ward and to attend to the patients in the absence of his principal In each hospital there are several of them, who in turn one at a time about once a week remain on the premises all night in readiness for emergencies. In the absence of the physician or surgeon and in cases of urgency the *interne* may perform some minor operations of which tracheotomy is one that formerly entailed some risks. These duties continue for four years, the remuneration is scanty, and the appointments are awarded in accordance with an annual competition, the candidates who come forward being five or six times as numerous as the vacancies, but as in all medical competitions at the present day favouritism is not always and entirely excluded. On the whole, it does not appear that the duties of an *interne* involve much more danger than falls to the lot of the students who are not *internes* and who every year lose some of their number by death from typhoid fever, diphtheria, tuberculosis, dissection wounds, &c. This being so, it was a little annoying to hear the *internes* lauded as if the good qualities which are the common property of the medical profession were concentrated in them and on that account the profession in general took no more than a languid interest in the *fêtes*, whilst the public celebration, presided over by a Cabinet Minister and occupying much space in the newspapers, seemed to betray a hankering after advertisement. This did not escape the notice of certain journals, and even of a portion of the non-medical press, the result being that while the ceremony at the Hôtel Dieu was in progress Professor Guyon, after having in the course of his speech mentioned the names of the *internes* who had died during their period of office, went on to say with graceful tact that it must not be forgotten that in the ranks of the medical men who did not belong to this particular class there were many who had greatly distinguished themselves and were not less imbued with the spirit of self sacrifice. A non-medical journal has even proposed that as a fitting pendant to the monument raised to the memory of the *internes* it would be desirable to have another monument commemorating all the medical men who had died victims to professional duty.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Anæsthesin.

THE ester of para-amidobenzoic acid, which has received the name of "anæsthesin" and is prepared by Dr. Ritsert at the Höchster Farbwerke, is recommended as an efficacious local anæsthetic and as a substitute for orthoform. Experiments on rabbits have shown that it is not dangerous even in considerable doses but that doses which are very large and altogether in excess of those employed in practice will produce hæmoglobinuria. In some clinical observations published by Professor von Noorden in the *Berliner Klinische Wochenschrift* it is mentioned that anæsthesin is especially efficacious in cases of gastric irritation and that patients suffering from gastric ulcer may take from three to five decigrammes (from five to eight grains) 10 or 15 minutes before food to prevent vomiting. The largest daily dose as yet employed was 2·5 grammes (38 grains). Given in tabloids it relieved the cough in bronchitis; in laryngitis more benefit was derived from inhalations of a 10 per cent. solution than from any other local anæsthetic, cocaine included. In the form of suppositories it gave great relief in tenesmus and hæmorrhoids and also in tenesmus of the bladder. Ointments containing anæsthesin were very useful in pruritus and intertrigo, and it produced beneficial effects when applied to ulcers as a dry powder. Oberstabsarzt Dr. Dunbar has written in the *Deutsche Medicinische Wochenschrift* recommending the new remedy for use in surgical practice; he gave subcutaneous injections of a solution containing 0·25 part of hydrochlorate of anæsthesin in 100 parts of water and found that the anæsthesia thus produced was sufficient for the performance of a variety of operations. Anæsthesin may eventually be applicable in ophthalmic practice.

The "Practical Year" of Medical Study.

Recent legislation with respect to medical education provides that every student after having passed the State examination shall, previously to becoming qualified, spend a year in practical work at a hospital or other medical institution. The Government medical department has now issued regulations for the distribution of this class of students among the various hospitals, the proportion of students to patients being one student to each 25 patients in university hospitals, one student to each 37 patients in municipal and other public hospitals, one student to each 50 patients in private hospitals belonging to religious corporations, one student to each 60 patients in ophthalmic hospitals, one student to each 100 patients in sanatoriums for consumptive patients, and one student to each 120 patients in lunatic asylums. The managing bodies of hospitals desiring to receive students for the "practical year" have to make application to the Government department which will decide whether the hospital shall be permitted to do so, for it is expressly laid down in the regulations that only those hospitals are eligible where (1) the physicians and surgeons are competent and willing to instruct the students in the practical work of a medical man; and (2) where an opportunity is afforded of conducting chemical and microscopical investigations. Hospitals requiring a fee from the students will not be registered as places where the "practical year" may be passed. The number of vacancies at the eligible institutions offering to receive students for the "practical year" is said to be much in excess of the demand; students will therefore have no lack of opportunities of obtaining the requisite instruction. As regards the ultimate net advantages of this extension of the medical curriculum, a great deal will depend on the particular methods of instruction selected. If the young men have to spend their time in writing clinical reports of cases, as they do in some of the large hospitals, they are not likely to derive much real benefit from their "practical year."

June 2nd.

Obituary.

GEORGE FOWLER BODINGTON, M.D. DURH., M.D. GIESSEN, M.R.C.P. LOND., F.R.C.S. ENG.

WE greatly regret to have to record the death, in his seventy-third year, of Dr. George Fowler Bodington, which occurred recently in Paris, where he had made his home since his retirement from practice. The eldest son of Mr. George Bodington, surgeon, of Sutton Coldfield, whose work as a pioneer in the out-door treatment of tuberculosis is now well recognised, George Fowler Bodington was educated for the medical profession at Queen's College, Birmingham. After taking the Membership of the Royal College of Surgeons of England and holding the post of house surgeon at Queen's Hospital, Birmingham, he visited, as a ship's surgeon, Natal and India. He spent some time practising his profession in the back settlements of Pietermaritzburg, where his fees were paid in elephants' tusks, of which he brought away some hundreds of pounds' worth as the fruits of about eight months' work. At that time the elephant still roamed the forests of Natal; life there suited Bodington's hardy frame and adventurous disposition and perhaps he may have sometimes regretted that he did not stay where he would have been certain to make his mark. However, he returned to England, married, and settled in practice at Kenilworth in partnership with the late William Bodington, F.R.C.S., his uncle. In 1866 he moved to Middlesbrough-on-Tees and thence to Saltburn, where he remained until called to take the management of a prosperous private asylum established by his father at Sutton Coldfield, near Birmingham. Brought into contact with the vivid medical life of that great city, Dr. Bodington became an active member of its various medical societies and afterwards bore a leading part in establishing the Birmingham Medical Institute of which he was one of the early presidents; he was also president of the Birmingham and Midland Counties Branch of the British Medical Association in 1876. He was at this time full of activity, taking an immense interest in all that made for social and political progress and in particular he associated himself with the late Mr. Dalrymple in the movement to obtain legislation for the care and control of inebriates. But meanwhile events happened of considerable importance: he lost his first wife and married again, while the asylum owing to the falling in of the lease had to be transferred to Ashwood House, Kingswinford, in Staffordshire. Unfortunately, the second Mrs. Bodington never enjoyed good health at Kingswinford, and after several years of trial Dr. Bodington decided to sell the asylum and to seek elsewhere in a more congenial climate a home for his family. After wandering for a year or two he

The Goulstonian Lectures

ON

SOME ABNORMAL PSYCHICAL CONDITIONS IN CHILDREN.

Delivered before the Royal College of Physicians of London on March 4th, 6th, and 11th, 1902,

BY GEORGE F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE I.

Delivered on March 4th.

MR. PRESIDENT AND GENTLEMEN,—The particular psychical conditions with which I propose to deal in these lectures are those which are concerned with an abnormal defect of moral control in children. Interesting as these disorders may be as an abstruse problem for the professed psychologist to puzzle over, they have a very real practical —shall I say social?—importance which I venture to think has been hardly sufficiently recognised. For some years past I have been collecting observations with a view to investigating the occurrence of defective moral control as a morbid condition in children, a subject which I cannot but think calls urgently for scientific investigation. It has long been recognised that such a deficiency may occur in association with those disorders of intellect which are ordinarily recognised as idiocy, imbecility, or insanity, and I suppose no one doubts the morbid nature of the moral defect in these cases, whether it be regarded as dependent upon the intellectual failure or not. But there are other cases which cannot be included in this category—children who show a temporary or permanent defect of moral control such as to raise the question whether it may not be the manifestation of a morbid mental state, but who nevertheless pass for children of normal intellect; it is this condition in particular which seems to me to call for careful observation and inquiry. The importance of some more widespread knowledge of these morbid states, if such they be, is very great, and although some of them persist into adult life, at no other period are the opportunities for investigating them so favourable as in childhood; for in early years the influence of environment has not yet become so varied and complicated as to be altogether beyond our gauge, and it is possible to obtain a more or less accurate and detailed history of the whole life of the individual, a point of extreme importance when the question of a congenital deficiency arises, as it will do in connexion with these cases: moreover, if there be any question of a morbid failure in the development of a mental process it can best be studied in the child, who is still at the age when, as we shall see, such development should be in progress. Whilst, therefore, I propose to consider generally the occurrence of defective moral control as a morbid condition in children, my particular object in this general survey is to determine what evidence there is on which we can base an answer to this question: Is diminution or defect of moral control in children ever the manifestation of a morbid mental state, apart from any such general disorder of intellect as is ordinarily recognised as imbecility, "feeble-mindedness," or insanity? and if so, under what conditions does it occur? It is obvious that such a disorder, if it exist, cannot be studied apart from its clinical phenomena, although some light may be thrown upon it by the consideration of the physical diseases or gross anatomical lesions which are associated with it in certain cases.

MORAL CONTROL IN THE NORMAL CHILD.

It is perhaps hardly necessary to define what is meant by "moral control." For the psychologist it is "the control of action in conformity with the idea of the good of all," and such a definition is at any rate sufficiently comprehensive for my purpose and may serve to correct the misapprehension which is apt to arise in consequence of the popular use of the terms "moral" and "immoral" to connote some sexual relation. The moral control to which I refer has a much wider significance, and its defect in any individual case may have, and indeed often has, no concern whatever with sexual relations; at the same time I would point out that such a definition will cover, not only such activity as is concerned with the good of others, but also with the good of self—in other words, the moral control which I wish to consider is not only the altruistic but also the self-regarding.

Moral control can only exist where there is a cognitive relation to environment. I use the term "cognitive" for lack of a better to imply that capacity for reasoning comparison on which moral control is necessarily based: the term "conscious" would imply too little, the term "intelligent" would imply too much. Out of this cognitive relation arises a consciousness of the relation of every volitional activity on the part of the individual to the good of all and this we may call moral consciousness. Moral control is the control of activity in conformity with this moral consciousness. The capacity for reasoning comparison may be regarded as an intellectual capacity and moral consciousness, inasmuch as it is concerned with more complicated relations, must require a higher degree of this capacity. To this extent moral control also is dependent on intellect; but inasmuch as volition also is concerned in moral control, and volition can hardly be regarded as an intellectual process, it would seem that intellect is not the only factor concerned therein, although it is an essential factor. To this point I shall return again when we come to consider the mental pathology, if I may so say, of defective moral control.

Moral control, it is obvious, is not an attribute of the newly-born child, for the infant only gradually comes into that cognitive relation which must precede the development of moral consciousness; moreover, moral control, as already pointed out, involves volition, and therefore cannot precede the earliest date at which activity ceases to be merely instinctive, reflex, or impulsive, and becomes volitional, a date which is extremely difficult to determine but certainly cannot be placed earlier than some weeks, or possibly months, after birth. Volition, in so far as it is concerned in moral control, may be regarded as inhibitory; it is the overpowering of one stimulus to activity—which in this connexion is activity contrary to the good of all—by another stimulus which we might call the moral idea, the idea of the good of all. There is, in fact, a conflict between stimuli, and in so far as the moral idea prevails the determining or volitional process may be regarded as inhibiting the impulse which is opposed to it. Now volition, as I have already pointed out, does not appear until some time after birth and the gradual and comparatively slow development of inhibitory volition, especially in regard to those forms of activity which are most instinctive and almost reflex in character, such as the expression of the emotions, is a matter of everyday observation, especially to those who have the opportunity of studying children.

Corresponding with this gradual acquirement of inhibitory volition in the normal child we recognise as a matter of general experience a certain rough proportion between the degree of stimulus which can be successfully opposed and the age of the child. I shall not attempt to define this in more accurate terms, for it is practically impossible to do so; but perhaps I may be allowed to illustrate my point by a simple example. An infant, aged 17 months, had been given a key to play with; he was sitting quietly on his mother's knee looking at the key which he held in his hand, when I gently took the key away from him and offered instead a sheet of white paper. The infant burst into passionate cries, bounded up and down on his mother's lap, beating the air with his fists, and when the paper was proffered beat it angrily aside. Here was a little ebullition of rage which was perfectly normal in a child of that age on provocation of that magnitude, but the same ebullition in a child, say of 12 years, on exactly similar provocation would have been altogether abnormal. My object in drawing attention to this point is to emphasise the fact that in considering the possibility of a morbid defect of volition as a factor in any case of defective moral control in a child, we must take into account not only the age of the child but also as far as possible the degree of the stimulus.

The possibility of moral control, as already pointed out, is the outcome of combined cognition, moral consciousness, and volition; but inasmuch as these are only gradually perfected or more fully developed as the child grows settled eventually in British Columbia where he purchased a farm and carried on medical practice, but it is doubtful whether these ventures were altogether successful. However, the advance of civilisation in these western regions rendered a large lunatic asylum a necessity of the province and of this Dr. Bodington was appointed medical superintendent in 1895. His success in this work is well attested by the following extract from the report of his successor: "It was apparent that to bring about the required changes would entail an immense amount of work and Dr. Bodington felt constrained through the advance of years to relinquish the labour to younger hands and seek well-earned rest and retirement in the land of his birth surrounded by the members of his family and his friends. In this connexion I can truthfully testify that no greater general sorrow has been witnessed throughout the institution than that occasioned by the departure of the one who had taken the helm at a very trying time, and had safely piloted the hospital through some difficult passages, giving to it his best energy and utmost attention, though never in robust health, and having already arrived at that period of life when men hope to be able to forget labour and worry. Dr. Bodington's resignation was accepted by the Government, who voted him a retiring allowance for his faithful services, which terminated on Feb. 28th, after six years of most arduous toil, during the greater part of which he was alone in the charge of the institution."

Dr. Bodington came to England last year to visit his relatives and to renew acquaintance with old friends. He eventually settled in Paris, where his eldest son, Mr. Oliver Bodington, occupies an important position in Anglo-American legal and commercial circles. His death occurred after a very short illness but his state of health had not been satisfactory for some time past. Dr. Bodington was a man of magnificent physique and fine presence, a delightful companion, and an enthusiastic man of letters. His second wife died some years ago, but he has left a large family of children settled in Europe and in Canada.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Louis Secretan, Professor of Internal Medicine in the University of Lausanne, at the age of 49 years.—Dr. Nicolas Kalindéro, Professor of Clinical Medicine in Bukarest.—Dr. Theodor von Kezmarsky, Professor of Midwifery and Gynæcology in the University of Budapest. To him is largely due the great amelioration which has taken place in the conditions under which labour has now for many years been treated both in hospital and in private practice in Hungary. He was only 60 years of age.—Dr. Clymer, formerly Professor of the Diseases of the Nervous System in the Albany Medical College.—Dr. W. D. Middleton, Professor of Surgery in the Iowa State University.—Dr. Franz Scholtz of the General Hospital, Vienna, at the age of 82 years.—Dr. Guido von Török, a well-known Austrian military surgeon who was Billroth's assistant from 1877 to 1880. His age was 52 years.—Dr. Karl Skrzeczka who succeeded Casper in the chair of Forensic Medicine in Berlin. He was 69 years of age and had lived in retirement for the last four years.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws have been admitted Members of the College:—

John Acomb, Yorkshire College and General Infirmary, Leeds, Charles Umpherston Aitchison, Oxford University and London Hospital; Evett Gordon Allport, Melbourne University and Guy's Hospital; Edward Whyte Aiment and Albert Maurice Amsler, St. Bartholomew's Hospital; James Vere Arkle, University of New Zealand and St. Thomas's Hospital; John Hilton Ashton, Owens College and Royal Infirmary, Manchester and Edinburgh; Sidney Marshall Banham, University College Hospital; Joseph Barnicot and Guy Douglas Barton, B.A. Camb., Cambridge University and St. Thomas's Hospital; Eric Bayley, Charing Cross Hospital; John Menlove Bennion, Cambridge University and St. Bartholomew's Hospital; William Benton, L.S.A. Lond., Charing Cross Hospital and London Hospital; Edward Bigg, B.A. Camb., Cambridge University and Guy's Hospital; Thomas Henry Bishop, Edinburgh and Durham University; Charles Edgar Blackstone, Middlesex Hospital; Arthur de Visme Blathwayt and Frank Elliott Bolton, University College Hospital; Frederick John Borrie, University of New Zealand and Middlesex Hospital; Leonard Bousfield, B.A. Camb., and Christopher Victor Bulstrode, B.A. Camb., Cambridge University and London Hospital; Gerald Lantsbery Bunting, Oxford University and Westminster Hospital; Philip Burnett, M.D., C.M. McGill, McGill University, Montreal, and St. Mary's Hospital; Harry Hendy Butcher and John Corbin, St. Bartholomew's Hospital; Marcus Woolf Cohen, B.A. Lond., Guy's Hospital; Horace Arthur Cutler, B.A. Camb., and Hugh Davies-Colley, B.A. Camb., Cambridge University and Guy's Hospital; Oswald Joseph Stanley Damian, St. George's Hospital; Augustus De Morgan, St. Mary's Hospital; Archibald Donald, M.B., M.S., D.P.H., Glasgow University and King's College Hospital; Hugh Reginald Dutton, Middlesex Hospital; John Evans, Guy's Hospital; Edgar Leonard Farncombe, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Tom Bower Fawley, University College, Sheffield, Yorkshire College, and General Infirmary, Leeds, and Guy's Hospital; Wilfrid Stephen Fox, M.A. Camb., Cambridge University and St. George's Hospital; Charles Edward Gaitskell, Guy's Hospital; Laurence Unthank Geraty, St. Bartholomew's Hospital and University Colleges, Dublin and Sheffield; Thomas Gibson, St. Thomas's Hospital; Douglas Gray, Charing Cross Hospital; William Harrington Gray, London Hospital; George Walters Greene, B.A. Camb., Cambridge University and London Hospital; Richard Griffith, Cambridge University and London Hospital; William Hackney, M.D., C.M. Trinity, Toronto, London, Ontario, and University College Hospital; Alexander Ritchie Hall, M.D., C.M. McGill, McGill University, Montreal, and University College Hospital; Langton Fuller Hanbury, St. Thomas's Hospital; John Joseph Hanley, Cork, Massachusetts, and Boston Universities; George Francis Innes Harkness, University College Hospital; William Henry Harwood-Yarred, B.Sc. Lond., St. Thomas's Hospital; James Gilkinson Higgins, St. Mungo's College, Glasgow; William George Hopkins, St Mary's Hospital; Norris Norman Allen Houghton, Guy's Hospital, Joseph Louis Howard, M.D. Cooper Medical College, Vienna and St. Mary's Hospital; Trevor Howell, University College, Cardiff, and St. Bartholomew's Hospital; Goldwin William Howland, B.A., M.B. Toronto; Adrian Russell Fortescue Hubbard, Charing Cross Hospital; George Frederick Humphreys and Percy Douglas Hunter, Guy's Hospital; Osburne Ievers, St. Mary's Hospital; John Jenkins, University College, Cardiff, and University College Hospital; Charles Percival Johns, B.A., M.B. Queen's University, Kingston, Canada, and University College Hospital, Edward Alfred Jones, M.B. Toronto, University College and Middlesex Hospital; Guy Hannah Kirby, Mason College, Queen's, and General Hospitals, Birmingham; Robert Hammersley Lee, King's College Hospital; Aaron Levy, B.A., M.D., C.M. McGill, McGill University, Montreal, and St. Bartholomew's Hospital; Alfred Edward Arthur Loosely, B.A. Oxon., Oxford University and St. Thomas's Hospital; George Edward Loveday, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; George Harvey Low, St. Bartholomew's Hospital; John Knowles Lund, Mason College, Queen's and General Hospitals, Birmingham, and Owens College and Royal Infirmary, Manchester; James McBryde, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Frederick William Marlow, M.D., C.M. Trinity, Toronto, and University College Hospital; George Maw, University College Hospital; Arthur George Hay Michel, Charing Cross Hospital; William Percival Miles, St. Bartholomew's Hospital; Frank Morgan, Westminster Hospital; Ratanji Mancherji Nanji, L.M.S. Bombay, Grant Medical College, Bombay, Arthur Charles Nash, Guy's Hospital; Courtney Llewellyn Nedwill, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; James Hardie Neil, M.B., Ch.B., New Zealand; Arthur Carr Osburn, Guy's Hospital; Leslie Johnston Paton, B.A., B.C., M.B. Camb., Glasgow and Cambridge Universities and St. Mary's Hospital; Drury Pennington, B.A. Camb., Cambridge University and St. George's Hospital; George Pereira, M.B., Ch.B. Edinburgh, Edinburgh University and St. Bartholomew's Hospital; Eric McLeod Perkins, London Hospital; William Pettigrew, University College Hospital and University College, Sheffield; David Jonathan Phillips, M.D., C.M. Canada, McGill University, Montreal, and London Hospital; Lawrence Pick, St. George's Hospital; Arthur Frederick Pilkington, St. Mary's Hospital; Charles James Pinching, B.A. Oxon., Oxford University and Guy's Hospital; Aubrey Keatinge Halliday Pollock, St. Bartholomew's Hospital; Robert Maurice Ranking, Cambridge University and St. Bartholomew's Hospital, Hugh George Rashleigh, Guy's Hospital; George Augustus Keppel Hart Reed, St. George's Hospital; Owen William Richards, M.A. Oxon., Oxford University and Guy's Hospital; James Riddell, M.B., B.S. Melb., Melbourne University and King's College Hospital, Henry Naunton Robson, St. Thomas's Hospital; Cecil William Rowntree, L.S.A. Lond., Middlesex Hospital; Arthur Reginald Schofield, London Hospital; Charles Newton Sears, St Thomas's Hospital; Walter Moray Shand, M.B., Ch.B. New Zealand, St Bartholomew's and Charing Cross Hospitals; Henry Finch Skrimshire, Cambridge University and Charing Cross Hospital; Herbert James Slade, St. Bartholomew's Hospital; Frank Wybourne Smith, Guy's Hospital; Robert Howard Newby Smith, London Hospital; James Arthur Smyth, University College Hospital; Robert Archibald Slater Sunderland, St. Bartholomew's Hospital, James Templeton, St. Mary's Hospital, William Edward James Tuohy, Guy's Hospital; Godfrey de Bec Turtle, Cambridge University, King's College Hospital, and Royal Infirmary, Newcastle; Harold Upcott, St. Thomas's Hospital; Arthur Beaumont Waller and George Stafford Ward, London Hospital. Noel Everard Waterfield, St Bartholomew's Hospital; Eugene Christopher Whitehead, Westminster Hospital; Owen Thomas Williams, B.Sc. Lond., University College, Liverpool; Reginald Cameron Wilmot, St. Bartholomew's Hospital; Herbert Pattison Wiltshire, B.A. Camb., Cambridge University and Guy's Hospital; William Wingate Wingate-Saul, M.A. Camb., Cambridge University and St. Bartholomew's Hospital; Guy Theodore Wrench, Guy's Hospital; John Henry Wroughton, St. Bartholomew's Hospital, and Bransby Yule, University College Hospital.

University of London.—At the M.B. examination in May the following candidates were successful:—

First Division.—Walter Fedde Fedden, St. George's Hospital, and Percival George Harvey, St. Bartholomew's Hospital.

Second Division.—Oswald Lacy Addison, University College; Frederick Cecil Edgar Atkinson, St. George's Hospital; Thomas Aubrey, University College, Bristol, and St. Bartholomew's Hospital; Edward Walter Bain, London Hospital; Hugh Barber, Owens College and Guy's Hospital; Percy John Cammidge, St. Bartholomew's Hospital; Ernest Philip Chennells, University College; Edward Murray Clarke, London Hospital; Hector Alfred Colwell, St. Bartholomew's Hospital; Agnes Emma Dunnett and Eric Evans, London (Royal Free Hospital) School of Medicine for Women; John Evans, Guy's Hospital; Edward Fow Fisher, London Hospital: David Forsyth, Guy's Hospital; John Gay French, St. Mary's Hospital; Frederick Goulburn Gibson, Guy's Hospital; Archibald Douglas Hamilton, University College, Liverpool, and St. Thomas's Hospital; Arthur Charles Haslam, St. Thomas's Hospital; Stanley Hodgson and Norris Norman A. Houghton, Guy's Hospital; Francis Musgrave Howell, St. Bartholomew's Hospital; William Henry Jones, London Hospital, Frederick Samuel Longmead and William Sydney Page, St. Mary's Hospital; Rees Phillips, Middlesex Hospital, Herbert Dean Pollard, London Hospital; David Thomas Price, St. Mary's Hospital and Bristol Medical School; Morgan James Rees, Guy's Hospital; Philip Savill, University College, Emily Gertrude Stuart, London (Royal Free Hospital) School of Medicine for Women, George Orissa Taylor, London Hospital; Vere Godsalve Ward, St Bartholomew's Hospital; and Lucy Wellburn, London (Royal Free Hospital) School of Medicine for Women.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

University of Cambridge.—Mr. F. G. Hopkins, Emmanuel College, is to be appointed Reader in Chemical Physiology. Emmanuel College has generously offered to contribute £100 a year to his stipend —Among the recipients of honorary degrees on June 10th will be Principal Rücker of the University of London; Sir Harry Johnston, discoverer of the okapi; and Dr. Bell, director of the Canadian Geological Survey.—On May 26th the following were admitted to medical degrees:—

Bachelor of Medicine.—H. T. Hodgkin, King's; A. de W. Snowden, Christ's; and F. E. Wood, Downing.

Bachelor of Surgery.—H. T. Hodgkin, F. D. Nicholson, and G. E. St.C. Stockwell, King's, C. V. Bulstrode, Trinity; G. E. Loveday, B. Spearman, and R. Spearman, Caius; A. de W. Snowden, Christ's; H. C. Butler, Emmanuel; and W. W. Jeudwine, Selwyn.

Mr. L. Doncaster has been appointed Assistant Superintendent of the Zoological Museum. The examiners for the Final M.B examinations are Dr. Isambard Owen, Dr. L. Humphry, and Professor W. S. Greenfield in Medicine; Dr. M. Handfield-Jones and Dr. G. E. Herman in Midwifery; and Mr. C. T. Dent, Mr. Ward, and Mr. E. Owen in Surgery.

Royal College of Surgeons in Ireland.—At a meeting of the Fellows held on June 2nd for the election of President, Vice-President, honorary secretary, and council for the ensuing year the following were elected:—President: Lambert H. Ormsby. Vice-President: Arthur Chance. Honorary Secretary: Sir Charles Cameron. Council: Sir Philip Smyly, H. R. Swanzy, E. H. Bennett, Sir Charles Cameron, Austin Meldon, J. B. Story, Sir W. Thomson, C. B Ball, T. Myles, J. Lentaigne, R. D. Purefoy, H. G. Sherlock, R. B. McCausland, R. H. Woods, T. Donnelly, F. T. P. Newell, J. D. McFeely, W. Taylor, and H. W. Oulton.

Aberdeen University Medical Society.—A meeting of this society was held on May 30th when Dr. Angus Fraser delivered an address, entitled, "A Retrospection." He reviewed in detail the great advances in the various branches of science made during the last 100 years. Commencing with the discovery of such elements as oxygen, nitrogen, and hydrogen about the end of the eighteenth century, he pointed out the great original inventions made in most branches of science by Englishmen. Reviewing the science of medicine in particular, he showed that it was chiefly in this country that the original discoveries were made which had advanced so much the science of medicine, although they might have been worked out in detail by other nations. In support of this he instanced the discovery of vaccination by Jenner, of ether by Morton, and of chloroform by Simpson. With regard to the works of Virchow and Koch on Cellular Pathology and Bacteriology respectively, he suggested that theirs was not work of an original kind, but that they elaborated the fundamental principles laid by Goodsir of Edinburgh and Villement and Pasteur of France. In concluding, Dr. Fraser referred to the great advance of Japan, not only in the commercial but also in the scientific world. A hearty vote of thanks was accorded to Dr. Fraser for his interesting and illustrative paper.

Royal Institution.—An extra Friday evening discourse will be delivered at the Royal Institution on June 13th at 9 o'clock, by Mr. G. Marconi, on the Progress of Electric Space Telegraphy.

Cottage Hospital for Tredegar.—At a meeting held on May 30th it was decided to erect a cottage hospital for Tredegar, upon a site of land given by Lord Tredegar, at a cost of £2000.

Donations and Bequests.—Mr. and Mrs. Pearson, Johnston Lodge, Laurencekirk, have given £600 to the Royal Hospital for Sick Children, Aberdeen, for the endowment of a cot to be named the "Pearson Cot."

Cardiff Seamen's Hospital.—At a recent meeting of the building committee of this institution it was reported that the sum received up to the present towards the new hospital amounted to £13,806 The committee decided to invite the Marquis of Bute to lay the memorial stone of the new building in August next.

Bristol Lunatic Asylum.—The Bristol Lunatic Asylum, where there is accommodation for 950 patients, has now been entirely lighted by electricity for a whole year and the cost during that period was £99 less than was that for gas during the previous year.

Bequest for a Nurses' Home.—The late Miss Mayzod Rowland, who died at Neath on May 25th, has left the sum of £2000 to build a home for the Queen's nurses at Neath or to be invested and the proceeds applied to the general purposes of the Neath Nursing Association. Miss Rowland also bequeathed £200 to the Porthcawl Rest and a like sum to the Children's Convalescent Home at Tollington Park, London.

Death of a Medical Man after Cycling.—An inquest was held at Langdon Hills, Essex, on May 30th, on the body of Mr. J. S E. Cotman, M R.C.P., L R.C.S. Edin., of The Minories, London, E.C., who was found on the greensward by the roadside at Langdon Hills on the evening of May 27th. The deceased gentleman, who was 54 years of age, went for a short bicycle ride to Langdon Hills, and was found lying by the roadside. He complained of a pain in the chest and asked the distance to the nearest railway-station. He died later. The cause of death was heart failure and exhaustion from excessive heat.

Nottinghamshire Sanatorium for Consumptives.—The Nottinghamshire Sanatorium for the Treatment of Consumption, on Ratcher-hill, Sherwood Forest, near Mansfield, was formally opened on May 30th by the Duke of Portland, in the presence of a large and representative gathering. The sanatorium is intended for the treatment of patients with limited means, and although it has been opened free from debt the income for its maintenance has to be provided. It is estimated that the expenses will amount to 30*s.* a week, or £75 a year, per patient, which with only 14 patients means £1000 a year, or for 20 patients £1500 a year. The committee hopes that there will be a large number of annual subscribers of one guinea (or more) who will thus become members of the association and form its governing body.

Robbery at a Coroner's House.—At West London Police-court on June 2nd Thomas King, aged 27 years, described as a furniture dealer, and Richard William Greenwood, aged 24 years, a labourer, were charged with being concerned in stealing an Indian necklet, a pair of gold sleeve-links, two gold bracelets, and other articles worth £30 from the house of Dr. F. J. Waldo, Holland-park, W. Dr. Waldo stated that on Sunday afternoon he was sitting in the drawing-room with his wife when he heard shouts and the cook cried out, "There's a man in the house." He immediately ran out of the room and pursued King through the grounds at the back of the house and while jumping the garden-wall close to the man's heels he caught his foot in the ivy and fell. He jumped to his feet and continued the chase. Finally he caught the prisoner in Lansdowne road where King made a show of resistance, but a constable arrived and took the man into custody. Police-constable Ingate said that while he was engaged with King Greenwood came behind him, dealt him a couple of blows, and threw him to the ground, saying "That's my pal." The whole of the stolen property was found in the coat-pocket of King Mr Lane, the magistrate, ordered a remand.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. R. U Wallace, M B. Lond , M R.C.S. Eng , has on his return to practice in Hackney received from his friends an illuminated address and a cheque for £700.

TROWBRIDGE COTTAGE HOSPITAL.—The Trowbridge (Wilts) Cottage Hospital has recently received a bequest of £1000 from the late Sir W R. Brown, a legacy of £500 from the late Mr T E. Exley, and a gift of £500 from Dr T. Jarvis Bennett.

RABIES.—In August, 1900, a boy and a man residing in the Llandilofawr district of Carmarthenshire were bitten by a rabid dog and were under treatment at the Pasteur Institute for nearly three weeks. Neither patient appears to have suffered any ill-effects until May 27th when the man, who was 66 years of age, was taken suddenly ill and developed symptoms of rabies, dying in great agony on the following day

THE LATE DR. EDWARD LONG FOX.—At a meeting held on May 29th it was decided to establish a memorial to the late Dr. E. Long Fox who had practised in Bristol for 43 years and who died on March 28th. Included in the memorial will be a tablet to be placed in the cathedral, an annual lecture at University College, Bristol, upon some subject connected with medical science and to be called "the Long Fox Lecture," and the partial supporting of a medical missionary student at University College, Bristol.

LITERARY INTELLIGENCE.—The following books will shortly be published by Messrs. J and A. Churchill the seventh edition of the Diseases of Children, by Dr J F Goodhart and Dr G F Still, with about 100 pages more than before and the page enlarged to the library form , the second edition of a Manual of Bacteriology, by Dr R. T Hewlett, Professor of Pathology and Bacteriology in King's College, London, much enlarged and with many new illustrations , the fourth edition of Volume II. of Fagge's Textbook of Medicine, under the editorship as hitherto of Dr P H. Pye Smith, F R.S , the second series of Clinical Lectures on Surgical Subjects, by Mr Christopher Heath , a new work by Dr A. T Schofield entitled, "The Force of Mind or the Mental Factor in Medicine" , and the fourth edition of the Schott Methods of the Treatment of Chronic Diseases of the Heart, by Dr W Bezly Thorne.

Parliamentary Intelligence.

HOUSE OF COMMONS

WEDNESDAY MAY 28TH

State of the Sewers at Westminster

MR. JOHN HUTTON asked the First Commissioner of Works whether he had had his attention called to the condition of the sewers in the neighbourhood of the Houses of Parliament and whether he could make any statement upon the subject.—Mr AKERS DOUGLAS replied: No complaints have reached me lately Some years ago attention was called to the unsatisfactory state of the sewers in the neighbourhood and a committee of the House of Commons reported on the need for improvements. The County Council considered, on representations from the Office of Works, methods for ventilating the metropolitan main sewer and the Council communicated with the vestry as to altering the district sewers under the charge of that body I think that very little has been actually done but some of the inlet ventilators in the street were altered My honourable friend is no doubt aware that as a result of an inquiry by a committee in [illegible], the drains of the Houses of Parliament were completely cut off from all risks from the public sewers.

The Hanworth Small pox Hospital.

Sir FREDERICK DIXON HARTLAND asked the President of the Local Government Board whether he had yet received the report of the two officers of the department whom he instructed to visit the site of the proposed small pox hospital at Hanworth Middlesex; and whether he was now prepared to take steps to prevent the danger to London which its erection above the intakes of three of the water companies might cause.—Mr WALTER LONG replied: Two officers of the department have visited the site of the hospital referred to and have made a report to me on the subject I understand that there is no fear of pollution of the sources of supply of the water companies provided that the cesspools on the site are emptied regularly and their contents are not allowed to overflow or soak away into the soil. I may add that as I am advised, there is no scientific evidence to prove that small pox infection can be conveyed by water, though no doubt any such risk should, if possible, be avoided.

FRIDAY, MAY 30TH

Lamp Accidents

Mr RITCHIE, in reply to a question by Mr H. C. RICHARDS, said that he was considering whether it might not be possible to institute some inquiry with special reference to the facts of the recent cases of death by burning

Home Office Affairs Lead Poisoning &c.

At this sitting of the House there was a long debate on the affairs of the Home Office and Mr RITCHIE in the course of his reply said that with regard to laundries he was not by any means satisfied with the present condition of the law Last year the Government did its best to amend the law and the House was familiar with the circumstances in which the Government was compelled to abandon its proposals. But he was not indifferent to the subject and he took immediate steps to communicate with the institution laundries and to obtain opinions from them which might afford guidance A great many replies had been received and, on the whole, they were favourable to an amendment of the law He had also been in negotiation with some of those who were most difficult upon the last occasion when legislation was attempted and he was hopeful that the Government might be able to propose soon—though, of course, not this session—some legislation which while not giving all that might be desired, would go a long way in the right direction He hoped that it would be possible to deal satisfactorily with the question of hours, the fencing of machinery and sanitation and if that were done it would be a great advance. Every one of the institutions with which he had communicated not only did not object to supervision in matters of that kind but many of them expressed a strong desire for supervision. In these matters no religious difficulty arose at all He felt strongly on this subject and he should not rest content until the law had been placed on a more satisfactory footing No doubt there had been a very marked improvement in respect of lead poisoning and it was clear that the operation of the law was leading to very satisfactory results The number of cases had been reduced from 457 a few years ago to 165 in 1901. Exemptions had been asked for by 33 manufacturers and he believed that applications were now coming in from 60 additional manufacturers, so that at present there were nearly 100 manufacturers who had seen their way to do something in connexion with this subject for the sake of some other advantages which were offered to them. In the fruit preserving trade the department had issued an order dealing with the lifting of heavy weights by young persons. He would seize every opportunity to give effect to the undertaking which he had given in connexion with this question Hon members should remember that the subject could not be dealt with by one order dealing with every trade, but the department had taken advantage of every fresh order in connexion with trades to impose conditions with regard to weight-carrying As to phosphorus-necrosis he thought the right hon baronet the Member for the Forest of Dean (Sir Charles Dilke) would not deny that what he called the revival of this disease was very small The number of cases had diminished in a remarkable way In 1898 there were 21 cases; in 1899 eight in 1900 three and in 1901, four What the right hon baronet called "a revival" must be the increase from three to four His hon friend the Member for Stoke (Mr Coghill) had asked him whether he would direct an inquiry into the general state of trade in the Potteries He did not think that the Home Office was the department to direct an inquiry If an inquiry were to be made, but he had heard now for the first time that the state of trade in the Potteries was so bad as to call for any exceptional treatment. If his hon friend would communicate with the Board of Trade he thought that he would find that they had much more information on the matter than they had at the Home Office With regard to the subject of experiments on living animals which had been raised by several members Mr RITCHIE said that as to the argument that animals suffered intense pain after recovery from the anæsthetic he was assured that that was not so because life was destroyed before return of consciousness. It might become necessary to appoint additional inspectors but it would be absolutely impossible to ensure that an inspector should be present at all operations for that would require an army of inspectors. No certificate was given except under every precaution that the operation would be conducted by a properly trained person for an adequate scientific object All possible means were taken to avoid causing animals unnecessary pain; the inspectors were most humane men and so generally were the operators. He did not know that there had been any convictions for cruelty under the Act.

MONDAY JUNE 2ND

Experiments on Living Animals

Mr BANBURY asked the Home Secretary whether he would state how many of the 9598 animals experimented upon under certificates A and A+E and A+F had been under the personal observation of the inspectors and in the case of animals experimented upon under these certificates which had not been under the personal observation of the inspectors what was the guarantee besides the word of the operator himself that the provisions of the certificates had been obeyed whether he would state at how many of the 1176 experiments on living animals in 1901 done under licence alone an inspector was present, and what was the guarantee, other than the word of the operator himself that the provisions of the licence as to anæsthesia were obeyed in the cases where an inspector was not present; also at how many of the experiments done under B and B + EL, numbering together (22) was an inspector present; and when experiments were performed under these certificates without the presence of an inspector what was the guarantee besides the word of the operator himself that the provisions of the certificates as to anæsthesia were obeyed; and whether he would state in how many experiments done under certificates A, A + E and A + F pain ensued before the main result of the experiment had been attained and who was the authority that decided whether or not pain did ensue —Mr RITCHIE replied Very few of the experiments under the certificates indicated or under the licences alone have been witnessed by an inspector but a very large number of the animals experimented upon have been seen and carefully examined by the inspectors and in no case have they found that an animal has been unnecessarily kept alive in pain. The licensee is, of course, responsible for carrying out the conditions of his licence and certificates and the additional guarantees are that the inspectors can judge whether the licensee is in the habit of obeying the conditions by the number which they see and in which they find the animals in a proper state and by the fact that whenever they find an experiment going on the provisions of the law with regard to anæsthesia are obeyed. Further guarantees lie in the character of the persons to whom licences are granted and the eminent persons who recommend them and in the fact that such experiments must be performed in registered places which are under the control of responsible authorities, and that all applications are carefully scrutinised before registration is granted

In the course of the sitting Mr. Banbury brought in a Bill to amend the Cruelty to Animals Act, 1876.

Cancerous Cattle.

Sir James Joicey asked the Home Secretary whether his attention had been called to a recent case at the Leicester County Court, before His Honour Judge Wightman, when a statement was made by one of the meat inspectors of the Leicester Corporation that in cases where cancer occurred in an animal (presumably local) he only condemned the part of the animal affected as being unfit for human food but passed the remaining part of the carcass; if so, whether, considering the increase of cancer in the United Kingdom, he would make regulations, or ask the local authorities to do so, to ensure in such cases the condemnation of the whole carcasses of animals in any way affected by cancer.—Mr. Walter Long, replying to the question, said: I have seen a short newspaper report of the case referred to. I am advised that the course adopted would appear to have been sufficient, and it does not seem to me that there is any need to ask local authorities to take action of the kind suggested. I have no power to make regulations on the subject.

Tuesday, June 3rd.

The Holding of Inquests.

Sir John Leng asked the Attorney-General whether his attention had been called to the holding of an inquest on a man, aged 70 years, who died lately in his own house at Mapplewell after being ill for more than three years suffering from cancer; if he would explain why an inquest was held in this case; and whether he would promote legislation to prevent inquests being necessary in such cases.—Mr. Ritchie replied. I find on inquiry that an inquest was held in this case to explain the reason of the deceased man's having a dislocation of the hip, complicated by fracture of the thigh bone, and that it was only after very careful attention to the medical evidence at the inquest that the jury were enabled to return a verdict to the effect that the death was purely natural, and that the injuries to the bones were the result of the cancerous growth and were not due, as had appeared possible, to a fall or external violence of some kind. Under these circumstances it seems impossible to say that the coroner did not properly exercise the discretion given him by the Act

Medical Provision in Orkney.

Mr. Cathcart Wason asked the Lord Advocate if his attention had been called to the fact that a petition from the island of North Ronaldshay, praying that telegraphic communication should be established with the mainland, was refused consideration by the Post Office owing to the extensive nature of the work; and whether, seeing that the population of the island was over 400, that there was no medical officer there, and that medical or surgical attendance could only be procured after considerable delay, he would consult with the Northern Lighthouse Commission, the Scotch Fishery Board, and the Congested Districts Board as to the establishment of communication by heliograph, semaphore, or pigeon post.—The Lord Advocate, in reply, said that the Secretary for Scotland was not prepared to initiate action in the direction indicated by the honourable Member. He would, however, be happy to consider any scheme for facilitating communication that might be laid before him by those interested.

Vaccination Exemptions.

Mr. Corrie Grant asked the Home Secretary whether he was aware that Mr. E. Dew made application to the Spelthorne Sessions, Staines, on Monday, May 5th, for an exemption certificate on the ground of conscientious objection to vaccination; that, four of the magistrates being in favour of granting the certificate and four against, it was refused; and, seeing that under the circumstances two of the magistrates who were in favour of granting the certificate could have signed the certificate, whether he would state what action he proposed to take.—Mr. Ritchie replied. I am advised that where a majority of the justices sitting in petty sessions are not in favour of granting a certificate of exemption from vaccination it would not be proper for any minority to grant the certificate unless the other justices present abstained from adjudicating in the case. There is no action which I can take in the matter.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Bean, Harold Knowles, M D, C.M., B Sc. Edin., has been appointed Government Medical Officer at Wallsend, New South Wales.

Brook, T. S., M R C S., L R C.P. Lond., has been appointed Medical Officer to the Petersfield Union.

Burritt, B. H., M.B Syd., has been appointed a Member of the District Board for Old age Pensions at Dubbo, New South Wales.

Claremont, Claude C., M.D., has been appointed Physician to the Royal Portsmouth and Gosport Hospital, vice J. Watson, appointed *Consulting Physician.*

Cole, Robert Hodgson, M.B. Durh., has been appointed a Coroner for Victoria.

Colmer, Ptolemy Augustus, M.R.C.S. Eng., L.R.C.P. Lond., L S.A., has been appointed Medical Officer and Public Vaccinator to No. 2 District, Yeovil Union.

D'Ombrain, Ernest Arthur, M.B. Melb., has been appointed Public Vaccinator for the South-Western District, Victoria.

Ercole, Quinto, M D., Ch.D. Bologna, has been appointed Government Medical Officer and Vaccinator at White Cliffs, New South Wales.

Elvins, Henry, F. H., M B. Melb., has been appointed Medical Officer of Health, *pro tem.*, for the Borough of Clunes, Victoria.

Eyre, J. W. H., M.D., has been appointed Bacteriologist to Guy's Hospital.

Floyer, F. A., B.A., M.B. Cantab., M.R.C.S. Eng., L.S.A. Lond., Civil Surgeon attached to Connaught Hospital, Aldershot, has been appointed a Government Medical Officer in the British Central African Protectorate, to proceed to Zomba.

Freemantle, Francis E., M B, B Ch. Oxon., has been appointed Medical Officer of Health to the Herts County Council.

Green, Reginald, M D., D Hy. Dunelm, has been appointed Medical Officer of Health and Medical Officer to Infectious Hospitals for the Kings Norton and Northfield Urban Council.

Holcroft, W. F, has been appointed Medical Officer for the North Molton and Molland Districts by the South Molton (Devon) Board of Guardians.

Lamb, William, M D., C.M. Edin., M.R.C.P. Lond., has been appointed Honorary Surgeon to the Birmingham and Midland Ear and Throat Hospital, vice Dr. Charles Warden, resigned.

Lynch, Peter, L R.C P. Edin, has been appointed Public Vaccinator for the Metropolitan District, Victoria.

McGee, William, L.K Q C.P., has been appointed Officer of Health for the Shire of Phillip Island and Woolamai, Victoria.

Macquarie, Charles Nicol, L.R.C.P. Edin, has been appointed Medical Officer of Health for the Shire of Omeo, Victoria, and Public Vaccinator for the North-Eastern District, Victoria.

Mahomet, Archibald, M.B., Ch B. Aberd., has been appointed House Surgeon to the Paddington Green Children's Hospital.

Morris, F. H., M D. St. And., has been re-appointed Medical Officer of Health to the Wellingborough Rural District Council.

Owen, Frederick James, M D. Melb, has been appointed Public Vaccinator for Needham District, Victoria (Acting), during the absence of Dr. Esler.

Reid, Matthew Alexander, M.B. Edin., has been appointed Acting Officer of Health for the City of Richmond, Victoria, during the absence on leave of Mr. Branson.

Symons, William Henry, M.D. Brux., L.R.C.P. Lond., M.R.C S., L S.A., D P.H. Oxon. and Durh., has been re-appointed Medical Officer of Health for Bath.

Tighe, John M., L.R.C.P. Edin., has been appointed Medical Officer of Health for the Shire of Yarrawonga, Victoria, during absence on leave of Dr. O'Sullivan.

Wilson, Geoffrey R, B.C. Cantab., has been appointed House Physician to the Paddington Green Children's Hospital.

Worthington, Sidney, M.D. Lond., F.R C.S. Eng., has been appointed Honorary Physician to the Chesterfield and North Derbyshire Hospital and Factory Surgeon for the Chesterfield District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ayr District Lunacy Board.—Medical Superintendent. Salary £500, with house, coal, gas, &c.

Brighton, Hove, and Preston Dispensary.—House Surgeon. Salary £160 per annum, with apartments, coals, gas, washing, and attendance.

Bristol City Lunatic Asylum.—Medical Assistant, unmarried. Salary £140 per annum, increasing to £160, with apartments, board, and washing.

Central London Sick Asylum at Cleveland-street or Hendon.—First Assistant Medical Officer. Salary £120 per annum, with board and residence at Hendon.

Central London Throat and Ear Hospital, Gray's Inn-road.—House Surgeon (non-resident). Honorarium at rate of 40 guineas a year.

City of London Hospital for Diseases of the Chest, Victoria-park, E—Second House Physician for six months. Salary at rate of £30 per annum, with board, washing, and residence.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Resident Medical Officer. A salary, with board, residence, and laundry.

Fisherton Asylum, Salisbury.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

Forres Leanchoil Hospital, Morayshire.—Medical Officer. Salary £60 per annum.

Glasgow, St. Mungo's College, Medical Faculty.—Notman Chair of Physiology

Great Northern Central Hospital.—Pathologist and Curator. Salary 50 guineas per annum.

Hartlepools Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

Hereford County and City Asylum.—Senior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing. Also *Junior* Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

Isle of Man Lunatic Asylum—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

Kensington Dispensary and Children's Hospital.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, coals, gas, and attendance.

Leicester Infirmary—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrar. Salary £100 per annum. Also Assistant Surgeon.

LONDON TEMPERANCE HOSPITAL, N.W.—Assistant Resident Medical Officer for six months. Honorarium at rate of 60 guineas per annum, with board, residence, and washing.

NORFOLK AND NORWICH HOSPITAL.—Second Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Assistant Physician.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried Salary £160 per annum, with apartments, attendance, light, and fuel.

PARISH OF FULHAM INFIRMARY, St. Dunstan's-road, Hammersmith, W.—Second Assistant Medical Officer for six months. Salary £80 per annum, with board, apartments, and washing. Also Locum Tenens for ten weeks, with remuneration at rate of £4 4s. a week, with board, apartments, attendance, &c.

ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square.—Lecturer on Dental Anatomy.

ROYAL EAR HOSPITAL, SOHO.—House Surgeon. Small honorarium.

ST. ANDREW'S HOSPITAL FOR MENTAL DISEASES, Northampton.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with board, apartments, and washing.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck street, Cavendish-square, W.—Resident Medical Officer. Salary £150 per annum, with apartments, attendance, coal, and light.

SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM, Bicton Heath, near Shrewsbury.—Medical Superintendent. Salary £850 per annum, with unfurnished house, fuel, light, &c.

SOMERSET AND BATH ASYLUM, Cotford, Taunton.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, and washing.

STAFFORDSHIRE COUNTY ASYLUM, Stafford.—Junior Assistant Medical Officer, unmarried. Salary £150, rising to £200, with apartments, board, &c.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing. Also Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

SUSSEX COUNTY HOSPITAL.—Second House Surgeon and Anæsthetist. Salary £70 per annum, with board and residence.

WILTS COUNTY ASYLUM, Devizes.—Assistant Medical Officer, unmarried. Salary £160 a year, rising to £190, with board, residence, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

CARLIER.—On May 26th, at Elvetham road, Edgbaston, Birmingham, the wife of Professor E. Wace Carlier, M.D., F.R.S. Edin., of a son.

COPEMAN.—On June 1st, 1902, at 57, Redcliffe-gardens, S.W., the wife of Sydney Monckton Copeman, M.D., F.R.C.P., of a daughter.

HEWETSON.—On May 27th, at Edmund-street, Birmingham, the wife of John T. Hewetson, M.D. Edin., F.R.C.S. Eng., of a son.

MURRAY.—On June 2nd, at Ravenscourt-park-crescent, Llandrindod Wells, the wife of John Murray, M.B., C.M. Glasg., of a son.

REISSMANN.—On April 29th, at Knutsford, Glenelg, South Australia, the wife of Charles Reissmann, M.A., M.B., M.R.C.P., of a daughter.

REYNOLDS.—On June 4th, at Highcroft, Shepherd's Hill, Highgate, N., the wife of Austin Edward Reynolds, M.R.C.S. Eng., of a son.

SMITH.—On May 30th, at 229, High-street, Watford, the wife of G. Francis Smith, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MARRIAGES.

CODD—LEESON.—On June 3rd, at Sutton Coldfield Wesleyan Church, by Rev. John Codd (father of the bridegroom), assisted by Rev. W. R. Dent and Rev. R. S. Armsby, B.A., John Alfred Codd, M.D., B.Sc. Lond., of Wolverhampton, Honorary Assistant Physician, Wolverhampton General Hospital, to Jennie, daughter of Mrs. Leeson of Sutton Coldfield and the late J. H. Leeson of Moseley, Birmingham.

HENDERSON—BRAMWELL.—On June 3rd, at St. Cuthbert's Church, Colinton, Midlothian, by the Very Rev. the Dean of Edinburgh, J. Hossell Henderson, Advocate, youngest son of the late George Henderson of Leghorn, Italy, and nephew of the late W. J. Ford, 17, Grosvenor-crescent, Edinburgh, to Mary, daughter of Byrom Bramwell, M.D., F.R.C.P.E., 23, Drumsheugh-gardens, Edinburgh.

LOW—ASHBY.—On May 31st, at St. Mary's, Staines, by the Rev. S. T. Wood, Vicar, assisted by the Rev. John Salway, cousin of the bride, Vincent Warren Low, M.D., B.S., F.R.C.S., of 27, Queen Anne-street, W., eldest son of Edward Low, Esq., of Staines, to Mabel, eldest daughter of John Ashby, Esq., J.P., of Staines.

DEATHS.

COTMAN.—On May 27th, suddenly, John Sell Edmund Cotman, M.R.C.P., L.R.C.S. Edin., L.S.A.

DOWN.—On May 28th, at 6, Ellison terrace, Streatham-common, George Down, M.D., M.R.C.S., L.S.A., late of Kensington and formerly of Kennington, aged 83 years.

GIBBON.—On June 3rd, at Abbey Hill, Bury St. Edmunds, Laura, the dearly loved wife of the Rev. Canon Gibbon, aged 77 years.

RODGERS.—On May 27th, at Corporation road, Cardiff, Florence Emily, the beloved wife of J. H. Rodgers, L.R.C.P., L.R.C.S. Edin.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

POLLUTED WELLS.

To the Editors of THE LANCET.

SIRS,—I shall be glad to know through THE LANCET what jurisdiction a medical officer of health has over a well which *is polluted and in his opinion the origin of an outbreak of enteric fever in a dwelling-house?* 1. Must the medical officer of health have the water *analysed* before condemning and closing the well? 2. Have the *rural district* council "power" to prevent the inmates of the house and neighbours *using the water* for drinking purposes *without first having the analyst's report on the water?* 3. In case of urgency has the medical officer of health discretionary powers to close a polluted water supply which in his opinion is the immediate cause of an outbreak of enteric fever without first notifying to the rural district council of his intention, where the *district* council meet only once a month, or must he conform to Section 70, Public Health Act, 1875?

I am, Sirs, yours faithfully,

June 1st, 1902. M. O. H.

*** 1. If our correspondent cannot persuade the owner or *occupier* to close the well he must put the facts before the clerk to the rural district council with a view to having a closing order applied for. The magistrate *may*—but it does not follow that he shall—order the water to be analysed or he may at once order the well to be *closed*. 2. The rural district council has no power other than through a magistrate's order. 3. Our correspondent should proceed as suggested under answer No. 1, and, if necessary, immediately inform the clerk who is then responsible for taking the consequent legal measures. In a matter of urgency the clerk would call a special meeting of the rural district council or sanitary committee.—ED. L.

THE LOCUM-TENENT AND COTTAGE HOSPITAL APPOINTMENTS.

PAX writes: "There is a small cottage hospital in a country town, where the patients are treated gratuitously by the medical men in the neighbourhood elected by the governors. In the event of one of these gentlemen being absent from home would his locum-tenent take his place as a matter of course without consent of the governors?" We think that it would be the best course for the locum-tenent to take the place of his principal automatically. Presumably the principal takes care, for the sake of his patients and himself, to be replaced by a competent man. The governors could hardly be expected to go into the *pros* and *cons* of a man's suitability to hold a temporary post at the hospital.

THE LAW FUND.

TRUSTEES: THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON.

SAM BROWNE BELTS FOR VOLUNTEER MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Volunteer medical officers will find the authority for wearing them (1) Volunteer Regulations, paragraph 917, p. 150, "As for officers of Royal Army Corps of corresponding rank." (2) Dress Regulations, appendix viii., p. 110, "Worn by officers of all branches of the service."

I am, Sirs, yours faithfully,
P. B. GILES, Brigade-Surgeon Lieutenant Colonel,
S.M.O. I., V.A.S. I.

Bletchley, June 3rd, 1902.

A CASE FOR DIAGNOSIS.

IN an "Account of the Author, from the Hand of a Surviving Sister," which is prefixed to the first volume of poems (1810) by the Rev. James Hurdis, D.D., Professor of Poetry in the University of Oxford, the circumstances of the author's death are thus described: "On Saturday, Dec. 19th, 1801, he went to Buckland in Berkshire and on the day following performed the whole of Divine service at that church. On the Monday evening he was attacked with a violent shivering, similar to that of an ague fit. On Tuesday he was unable to rise from his bed, complaining of great inability and heaviness upon his eyes, which prevented him from opening them. Every medical assistance was procured but to little effect, as he expired, apparently in a sound sleep, on the Wednesday evening, in his thirty-eighth year." It is a pity that no indication of the line of treatment adopted is given, but at that time bleeding was customary and was doubtless practised in this case. It certainly seems strange that a healthy young man should die "in a sound sleep" after an illness of only 48 hours In a letter to the poet Cowper, of which a copy is given in the "Account," Dr Hurdis himself alludes to the death of another sister in the following terms: "I watched by her nine-and thirty nights. I have seen my amiable and affectionate Catharine gradually put to death by a disease at once painful and lingering She had suffered extremely, and for nearly a week before her death had only short intervals of sense, in which she was unable to articulate her wants In the evening on which she died her senses returned, and she acknowledged us all, *rewarding us with many thanks for our attention to her.* She was then seized with a difficulty of breathing and slight convulsion, which did not appear very alarming to me, because I had seen her recover from the same symptoms before. I was the only person in the room when these began to abate, and she seemed to fall into a sound sleep, breathing without difficulty. I sat beside her, looking in her face, and the ease with which she slept soon inclined me to nod I almost fell from my chair more than once, and being apprehensive that I might disturb her if I persisted I went into the next room, to lie down upon a mattress which was on the floor. I met my eldest sister at the door, and desired her to give me notice when I was wanted I had scarce laid myself down when she came and informed me that her breath had ceased. I returned immediately into the room and was witness to two slight efforts made by nature to recover the action of the lungs, which not being attended with success she gave up the contest without deranging a single feature. The eyelid was still closed, the hand reclined upon the side of the easy chair, into which she had been partly raised from the bed, and not one attitude of the composure in which I left her had been disturbed "

FOREIGN EYE CLINICS

To the Editors of THE LANCET.

SIRS,—I should be glad if you could tell me where I could obtain information respecting fees, cost of living, &c, at the different "eye clinics" in Germany and Austria. Is a knowledge of each language a necessity? If any reader of THE LANCET would oblige with a brief summary of his personal expenses and experience it would be deemed a great favour I am, Sirs, yours faithfully,

June 2nd, 1902. THECLA W-ALBUM.

THE INJECTION OF COCAINE AND THE MORPHIA HABIT.

To the Editors of THE LANCET.

SIRS,—I have a patient who has contracted the morphia habit. He injects daily seven or eight tabloids of morphia sulphate (one-eighth of a grain) and atropia sulphate ($\frac{1}{300}$th of a grain). I should be glad to hear if any of your readers have tried to counteract the habit by the injection of cocaine and, if so, what doses would they advise?

I am, Sirs, yours faithfully,

May 30th, 1902. F. G B.

WANTED—A HOME

To the Editors of THE LANCET

SIRS,—Can any of your readers inform me of a home or institution suitable for a feeble-minded girl, aged 18 years, belonging to parents of the working-class? I am, Sirs, yours faithfully,

B. BROWN, M.R C S. Eng, &c.

3, London road, Bromley, Kent, June 2nd, 1902.

THE "Y" FUND.

SURGEON GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Dr. L. G. S Molloy (Blackpool), Dr. J A. Rigby (Preston), Dr. J. Gordon Black (Harrogate), Dr. W A. Elliston (Ipswich), Dr. H. Townsend, Mr S. Chard, Colonel Warburton, I M.S. (retired), Lieutenant-Colonel C K Powell, I M S (retired), Major A. Coleman, I M S, and the following officers of the Royal Army Medical Corps: Colonels J J Macnamara and A. W. Duke; Lieutenant-Colonels W W. Kenny, O'B. White, J. Barrye, W. Donovan, C.B, Ward, F P. Nichols, and G A. Hughes, D S O, Majors R. H Penton, D S O, J V. Salvage, J. W. Cockerill, Barnett Wilson, E. M Hassard, A. B Cottell, and J. M. Irwin, and Captains H W. H. O'Reilly and J D Alexander. The fund now amounts to £224. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington gardens terrace, Hyde Park, London, W

THE PREHISTORIC REMAINS RECENTLY ACQUIRED BY THE BRITISH MUSEUM.

To the Editors of THE LANCET.

SIRS,—I do not think that the inference drawn by Mr R Henslowe Wellington in his letter appearing in your issue of May 3rd, p 1293, with reference to the reconstructed burial in the British Museum is warranted by the facts I have recently had an opportunity of seeing the prehistoric cemetery in the Girga province here, which is being excavated with the most minute care and accuracy by Dr G. Reisner of Harvard University and his assistants, and I do not think there is any doubt whatever that the bodies were actually laid on their sides for burial, either in mats or baked clay coffins, and that this position is not due in any way to gravitation If this were so it would be difficult to account for the regularity with which the bodies in this cemetery are found on the left side. I may say that the site shows no signs of having been disturbed and many of the bodies are almost perfectly preserved (not by artificial means), though the date of their burial may be put at somewhere before 3000 B C.

I am, Sirs, yours faithfully,

Kolosua, Upper Egypt, May 23rd, 1902. A. T. WHITE.

◆

B. T. R—1 By the provisions of Section 4 (2) of the Notification Act, 1889, it is enacted that "the local authority . shall pay to every medical practitioner for each certificate duly sent by him in accordance with this Act a fee of 2*s*. 6*d*. if the case occurs in his private practice, and of 1*s*. if the case occurs in his practice as medical officer of any public body or institution.' The parish cases referred to by our correspondent would come under the 1*s* group. He would find a copy of the Infectious Disease (Notification) Act, 1889, useful for purposes of reference. 2. (*a*) There is no provision for the payment out of the public funds for the revaccination of children under 10 years of age, and our correspondent will, we think, find this *proviso* in his contract with the guardians (*b*) Similarly the contract will show that the fee for revaccination at the home of the patient is not the same as that for revaccination performed *elsewhere* than at the home of the person revaccinated. (*c*) As a public vaccinator cannot, in his official capacity vaccinate or revaccinate persons resident outside his vaccination district the guardians have no power to pay for such vaccination The clerk is, we think, right on every issue and we should counsel B T. R. not to press the matter further He should make himself quite familiar with his contract and procure for reference "Shaw's Manual of the Vaccination Laws," published by Shaw and Sons, Fetter-lane, Fleet-street

K I.T—It is a very usual, but a most irregular, practice for relieving officers to procure an informal certificate from the medical attendant of a person alleged to be of unsound mind before they remove the patient to the workhouse, so that this may, if necessary, be shown in justification of the removal. This is a practice which all medical men should be aware of and studiously avoid, for such a certificate is not covered by law and they run great risks of an action at law by the patient after recovery or by his friends. If it was a certificate of this kind which our correspondent gave he can claim no fee—indeed, he may think himself fortunate if he escapes the action at law to which we have referred. If, on the other hand, the certificate he gave was on the form prescribed by the Commissioners and at the request of a justice of the peace conveyed to him through the relieving officer, he will be fully entitled to such fee as the justice orders and the guardians have no option but to pay.

Locum Tenent—We do not think any time can be stated when the proceeding would be unobjectionable A locum tenent should never return to a locality where he has been doing the work of other medical men in return for a salary Whatever his real idea may be, it must always appear that he has returned in the hope of detaching patients from a previous employer. Our correspondent will understand that our reply is based upon the general question, he has mentioned no particular circumstances.

S. W, M D—Our correspondent will find the information he seeks in a work entitled "Clinical Hæmatology," by Dr J C Da Costa, jun; published by Rebman, 129, Shaftesbury avenue. By the word "hæmatology" is understood "the science of the blood, its nature, functions, and disorders."

Degree.—Any man possessing a doctorate given by a recognised university is a "doctor." Medical men are sometimes styled "doctor" because they happen to possess such a degree and sometimes because it is the time-honoured and popular method of addressing them.

Spero and other correspondents who have written to us on the subject of the proper "kit' for medical officers in the Yeomanry and Volunteer corps will find their questions answered under the heading of "The Services" on p 1642 of our present issue

Public Vaccinator is thanked for sending us the newspaper cutting The subject of vaccination fees is at the present moment under the consideration of the President of the Local Government Board

J. C L—No.

During the week marked copies of the following newspapers have been received:—*Hong Kong Daily Press, Allgemeine Medicinische Central-Zeitung, Il Policlinico Aberdeen Free Press, Rivista Medica de San Paulo Echo, Bristol Mercury, Liverpool Daily Post, La Caducée, Hong Kong Weekly Press, Times of India, Reading Mercury, Local Government Chronicle, Hertfordshire Mercury, Windsor and Eton Express, Sunday Magazine, Kensington News, St James's Gazette Ibero-Americana de Ciencias Médicas, Pharmaceutical Journal, Manchester Guardian Dublin Evening Telegraph, Southampton Echo, Coventry Herald, Belfast News, Birmingham Daily Mail, Scientific American, Literary Digest (New York), &c.*

CHARING CROSS HOSPITAL.—4 P.M. Dr Murray: Demonstration of Medical Cases. (Post Graduate Course.)

FRIDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr R. Lake: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr Reece: Chronic Poisoning by Minute Doses of Lead and Arsenic.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
	£1 12 6	One Year	£1 14 8
One Year	0 16 3	Six Months	0 17 4

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testmionials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W H Smith and Son s and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnières, Paris.

Presidential Address

ON

THE ANNUAL VARIATION OF PUERPERAL FEVER COMPARED WITH THAT OF SOME ALLIED DISEASES.

Delivered at the Opening of the Session of the Hunterian Society

BY A. L. GALABIN, M.D. CANTAB., F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—In selecting a subject for a short address on the commencement of my duties I have chosen one which is connected with my own speciality but is related also to general medicine and surgery—namely, the variation in prevalence of puerperal septicæmia in different years as compared with that of certain allied diseases—erysipelas, general septicæmia and pyæmia, scarlet fever, and acute rheumatism. The method I have followed is not a novel one but is in the main that adopted by Dr. G. B. Longstaff in his work, "Studies in Statistics," published in 1891. In this work is a table, which I have reproduced in part in my "Manual of Midwifery," showing, by the graphic method of curves, the variations of the above-mentioned diseases, as well as several others, for the 25 years 1855–1880 in England and Wales. I now present to you two diagrams (Figs. 1 and 2) showing the variations of these five diseases. One refers to England and Wales and includes 19 years—1881–1899—commencing after the end of those years tabulated by Dr. Longstaff. The other refers to London and includes the 20 years 1881–1900. The figures are taken from the reports of the Registrar-General, but these, unfortunately, are published only a long while after the date referred to. Thus the annual report for 1900 is not yet published and I cannot therefore carry the statistics for England and Wales further than the end of 1899. By using, however, the short annual summary of weekly reports I am enabled to carry the statistics for London to the end of 1900 and so complete the 20 years. These annual reports of the Registrar-General have thus only a retrospective interest in any bearing they have upon medicine or surgery, for a warning nearly two years after date of any existing or threatened epidemic prevalence of disease is too late to be of service. In the weekly reports too many diseases are grouped together to furnish information as to the prevalence of any one except a very few zymotic diseases. It appears a great pity that there cannot be given at least in the quarterly reports as much information as to the prevalence of particular diseases both in England and Wales and in London as is now to be found for London only in the short annual summaries of weekly reports.

The following is the plan which I have adopted in constructing the diagrams. The curves by their ordinates represent the percentage above or below the mean of the mortality of the disease in question for any given year. This is the method of representation followed by Dr. Longstaff, and before him by Buchan and Mitchell in the *Journal of the Scottish Meteorological Society* for 1874 It avoids the difficulty which would otherwise exist in comparing the curve of a disease having a high mortality with that of one having a comparatively very low one and allows the relative variations of each to be readily seen. I have not, however, taken the figures from the mortality of the different diseases per 1,000,000 living, as given in the Registrar-General's reports, according to the estimated population. I have taken the actual number of deaths for each year and first reduced each of these to the percentage above or below the mean and embodied them in curves. The mean, as corrected for population, is there represented as a slightly ascending diagonal line for each of the 10 years 1881–1890, 1891–1900, according to the results of the censuses in 1881, 1891, and 1901. It is then easy to see in this preliminary diagram the percentage of mortality in each year above or below the corrected mean. Thus a second diagram is constructed in which the mean is reduced to a horizontal line, as in the figures before you. This method ought to be somewhat the more accurate, since of late years each census has shown that the estimated population has been put too high both for England and Wales and for London.

The uppermost curve on each diagram represents the annual rainfall in inches at Greenwich. This is an inverted curve, the ordinates being drawn from above downward, so that each elevation of the curve represents a minimum and each depression a maximum rainfall. The reason for inverting the curve in this manner is that it is found that, on the whole, a minimum rainfall generally corresponds to a maximum mortality from the diseases in question, and a minimum rainfall to a maximum mortality, a result which may at first sight appear surprising as regards acute rheumatism. It must be admitted, however, that this relation is by no means clear or decisive in the 20 years under consideration. A dry year in 1884 is associated with a slight maximum in two only of the curves—that of erysipelas and that of septicæmia. A dry year in 1887 is associated with a maximum in three curves—puerperal fever, erysipelas, and scarlet fever; a less extremely dry year in 1890 with a slight maximum in four curves—puerperal fever, erysipelas, scarlet fever, and rheumatic fever. The most marked association is that of the dry year 1893 with an isolated maximum which is the most prominent feature of four out of the five curves throughout the whole 20 years, that of septicæmia being excepted, and which is more developed in London where one would expect the association with rainfall at Greenwich to be closer than in England and Wales. In observing more particularly the peculiarities of 1893 it is notable that it followed another year, 1892, which was dry though less extremely so; and that in one of its quarters, April to June, there occurred the minimum quarterly rainfall of the whole 20 years—namely, 1·47 inches. There was also a second period of drought, less extreme, for eight weeks in August and September and a large proportion of the whole rain of the year fell in six weeks, the eighth, ninth, twenty-eighth, forty-first, forty-second, and forty-sixth weeks of the year, only one of these lying between the beginning of March and the end of September.

Thus far there appears a distinct association of dry seasons with maximum mortalities of the five diseases. But since 1893 there have been two dry years, 1895 and 1898, occurring singly, and not associated with any maxima of these diseases but rather with minima. But in these years the rain has been more distributed. Thus while in 1893 there were only 27 days on which rain fell in the four months March to June, in 1895 there were 45 and in 1898 57. In the diagram constructed by Dr. Longstaff for the preceding 25 years, 1855–1880, there appears a much closer correspondence between maximum mortalities of these diseases and minima of a curve constructed by adding together the percentages above or below the mean of the amount of rainfall and the number of days in the year on which rain fell. The conclusion is that there is a connexion between unusual dryness and excessive mortality of these diseases, but that this connexion has not been apparent since 1894, having probably been overbalanced by other causes of improved mortality.

The meteorological character of the seasons might increase the prevalence of disease either by promoting the growth of pathogenic microbes outside the body or by facilitating their diffusion or conveyance. It appears inconceivable that a dry season can, while it lasts, promote the growth of microbes outside the body, or even help to preserve them alive, though it can be readily understood that damp ones might do so. If very dry periods therefore promote the spread of microbic diseases the probable conclusion is that they do so by aiding the dissemination of microbes in the form of dust. An example may be cited tending to show the occasional importance of dust conveyance of contagion even in the case of enteric fever, which is generally water borne—namely, the recently reported case of Bermuda. In Bermuda, enteric fever had long been very prevalent, so long as the dry earth system of latrines was in use. On the change of this system to that of water-borne sewage the prevalence of the disease was greatly diminished. It is obvious that the water-borne sewage would increase, rather than diminish, the risk of contamination of water, while the dry earth system might promote the conveyance of contagion by dust.

In order to test whether the effect of drought on the spread of disease is immediate and direct I have constructed a diagram (Fig. 3) showing the weekly variations of the

older, it is evident that the further development of moral control must also be a gradual process. The capacity for such development is present, we may reasonably assume, in the normal infant at birth, and so far there is an analogy, not to say connexion, between moral control and general intellectual acquirements; moreover, both are largely dependent on training and environment for their increase. This gradual growth of moral control in the normal child is a point to be remembered when we come to consider how far defective control is to be regarded as a morbid manifestation, for it follows that a degree of moral control which may be perfectly normal in a very young child may be altogether below the average for a child a few years older. Further, we must recognise that the development of moral control varies considerably in different children at the same age; such variation is no doubt in part the result of environment, but partly also, it seems possible, the result of differences in the innate capacity for the development of such control. To this important point I shall refer more fully hereafter; here I will only say that whilst the degree of development of moral control in children at various ages falls in the large majority of cases within a limited, albeit ill defined, range of variation which we arbitrarily recognise as normal for the age, there are children in whom moral control falls so far below this standard that the question may well be raised whether in such cases the defect is not the manifestation of some morbid psychical condition. In seeking the answer to this question it will, I think, be best to consider, first, defect of moral control in association with general impairment of intellect, for here, at any rate, it will be allowed that the moral failure is a morbid phenomenon.

DEFECT OF MORAL CONTROL ASSOCIATED WITH GENERAL IMPAIRMENT OF INTELLECT.

Morbid defect of moral control in children is most often seen in association with idiocy or imbecility and this association calls for special attention, as it is here that the relation of moral control to intellect can be studied most easily, inasmuch as grades of intellectual capacity are here more easily discernible and therefore more readily available for comparison; moreover, it will, I think, be seen that it is in idiocy or imbecility that we can most easily discriminate between certain differences in the causation of moral defect. In the lowest grade of idiocy moral control is necessarily an impossibility. The drivelling idiot who recognises no one, does not distinguish his food, and is little more than a mere automaton stands in little or no cognitive relation to his surroundings and *a fortiori* lacks that higher form of reasoning comparison which we call moral consciousness. Here, therefore, the absence of moral control is complete. Such cases are of interest chiefly as exemplifying one cause of failure of development of moral control; they have otherwise little bearing on the question before us and need not detain us further. I may, however, point out that in considering cases with any degree of general impairment of intellect caution is required in accepting absence of activity as evidence of moral control; the idiot of low grade does not steal nor, perhaps, does he behave spitefully, but this is not to be attributed to moral control but to the absence of stimulus owing to the fact that he is not in cognitive relation with his environment; and going further one may say that where there is a cognitive relation only to a limited portion of environment to that extent stimulus is limited and the corresponding activities will be absent. For instance, the idiot whose intellectual impairment is such that he has no appreciation of the value of money and does not distinguish it from other objects and has no pleasure even in mere acquisition does not steal, whilst a higher grade idiot who knows the use of money or takes a delight in mere acquisition does steal. To contrast two such idiots as showing in the former case moral control and in the latter its defect would be entirely fallacious; the absence of stealing in the former is due to the absence of stimulus—that particular idiot is, so far as money is concerned, cut off, if I may so say, from his environment.

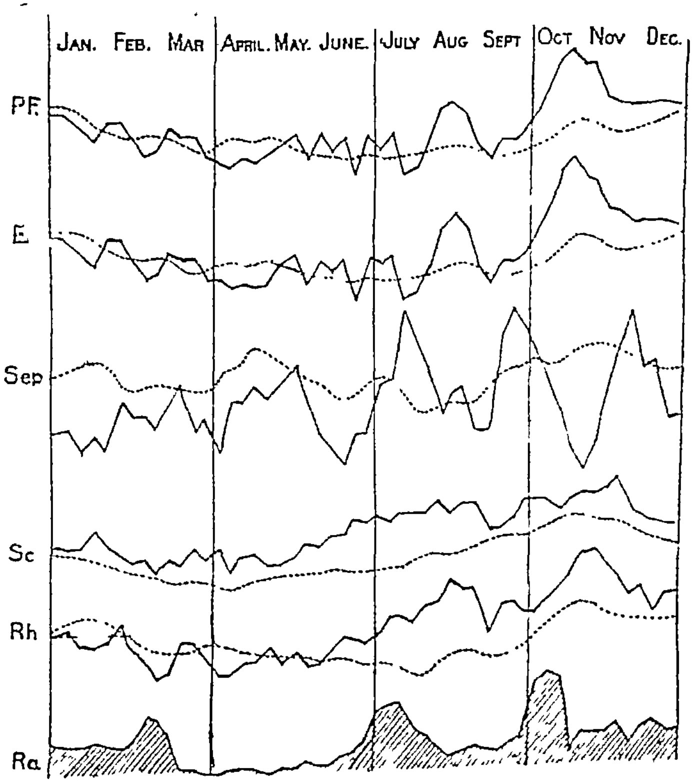
With this caution we may turn to the consideration of idiots of higher grades, and the first point which calls for attention is the frequency of defective moral control in these children. Of 90 consecutive imbeciles from three to 12 years of age under my own observation 23 showed a lack of moral control which was quite unnatural for the age of the child. It must not, however, be supposed that any one of these children showed every possible manifestation of moral deficiency; indeed, with a morbid defect of moral control from any cause, while it is probable that there will be several manifestations, it is quite unusual for all the possible manifestations to be present. Lack of moral control may be shown in many ways, and it will be convenient to have before us a list of those qualities which in their corresponding activities make up the picture of morbidly defective moral control, as it is seen not only with general impairment of intellect but also, as I shall show, with other conditions in children. These qualities are—(1) passionateness; (2) spitefulness—cruelty; (3) jealousy; (4) lawlessness; (5) dishonesty; (6) wanton mischievousness—destructiveness; (7) shamelessness—immodesty; (8) sexual immorality; and (9) viciousness. The keynote of these qualities is self gratification, the immediate gratification of self without regard either to the good of others or to the larger and more remote good of self. Some of these qualities, it will be observed, are natural to children at a certain age and to a certain extent; it is their persistence in a degree unusual for the particular age and not corresponding to the influences of environment which constitutes their abnormality in these children. Of the 23 cases which I mentioned 20 showed an abnormal degree of passionateness which in most of the cases was associated with other manifestations of defective moral control, but no one of these was so frequent as passionateness which in two of the cases appeared to be the only manifestation. This predominance of passionateness amongst the phenomena of defective moral control in children with general impairment of intellect is, I think, worthy of notice, for we shall find that not only in these children but also in many of the various conditions under which morbid diminution or defect of moral control occurs passionateness is the commonest of all its manifestations, and, as I shall show, this fact may throw some light on the psychical defect in these cases.

Next in order of frequency is spitefulness or cruelty which was a noticeable feature in 12 out of the 23 cases—I mean by this the wanton infliction of pain or discomfort on others; in my own observations I have somewhat arbitrarily restricted the term "spitefulness" to this tendency when it referred to infliction of pain or discomfort on other human beings, whereas when it was displayed towards the lower animals I have distinguished it as cruelty. Such cruelty was less frequent than spitefulness, it was noted only in two of the cases, but this may have been because there was less often opportunity for its display.

As a third prominent characteristic of deficient moral control not only in imbecile children but also in those whom I shall consider later, with no obvious intellectual deficiency, I may mention lawlessness. I have no figures to show its actual frequency, which, however, I fancy is very considerable. By lawlessness I do not mean, of course, the occasional or even frequent failure to conform to law—whether it be nursery law, school law, or the law of the land—which in greater or less degree is natural to children, but a reckless disregard for command and authority in spite of such training and discipline as experience shows will render a healthy child law-abiding to a certain roughly definable degree varying with the age. The other manifestations were all less frequent, and as I shall have occasion to illustrate them by actual cases I need say little about them here. By jealousy I mean, of course, not the mere emotion but its uncontrolled expression. Shamelessness and immodesty I have placed together as near akin to one another, for both are emotional qualities concerned with the relation of self to others. The essential element in both is an emotional shrinking from exposure to others, whether the ground of such shrinking be fancied or real, and this implies not merely the lowest and simplest form of cognition but also a capacity for reasoning comparison with regard to more complex relations which must approach, if it does not actually reach, the level of moral consciousness. As might be expected, therefore, in imbeciles of low grade both shame and modesty are often lacking, and I would add that it is by no means uncommon with impairment of intellect in children to meet with a curious absence of shyness or reserve, which may be included under the heading immodesty and which may have similar results so far as violation of social custom is concerned. In the idiot of low grade such a condition scarcely attracts notice, for the inability to discriminate between persons or between the different relations of the particular idiot to those persons is sufficiently explained by the profound intellectual deficiency; but in the child who is only slightly backward five diseases in London for the remarkable year 1893, in which four of them showed a high maximum of mortality. The numbers are reduced to percentages above or below the mean; and to render the curves more continuous I have adopted what is known as Bloxam's method. Instead of taking the mortality of each single week as the ordinates of the curve I have taken the mean mortality of each consecutive three weeks. This method tends to eliminate casual variations when the number of cases under consideration is not great enough to eliminate them. The continuous lines show the weekly variation of the five diseases in 1893; the dotted lines the mean weekly curves calculated from the 10 years 1883–1892. It will be seen that the scarlet fever mortality is above the mean of the season throughout the whole year. The chief excess occurs through the second half of the very dry period and two months following, a great part of these being also a period of drought. But, on the contrary, the excessive mortality of puerperal fever, erysipelas, and rheumatic fever does not occur in the dry period but forms an excess of two normal rises—one in August and the other at the end of October. Each of these culminates from two to four weeks after a heavy rainfall. It would seem, therefore, that in scarlet fever drought may directly promote contagion by the spread of dust, but that in septic diseases and rheumatism the effect only appears after an intervening rainfall and lapse of time. This would look as if it implied a growth of microbes outside the body following their dissemination, for the interval is too great to be simply due to time occupied in the development of the disease, especially since the greatest maximum of mortality did not occur till the end of October.

Comparing the mean death-rates per 1,000,000 living in England and Wales for the five diseases, the number for puerperal fever is 75, for erysipelas 54, for septicæmia and pyæmia 13, for scarlet fever 247, and for rheumatic fever, including rheumatism with affection of heart or pericardium, 88. In estimating the mortality of puerperal fever it must be remembered that it is limited to one sex and to a comparatively small number of years in the prime of life. Among the relatively large number of deaths from scarlet fever a great proportion occurs in children. It is a notable fact that the mortality of puerperal septicæmia is nearly six times as great as that of all other forms of septicæmia and pyæmia together. For London the mean death-rate of puerperal fever is 9·3 per cent. lower than for England and Wales; of erysipelas, 14·7 per cent. higher; of septicæmia and pyæmia, 46·1 per cent. higher; of scarlet fever, 0·8 per cent. lower; and of acute rheumatism, identical. The specially high excess in London for septicæmia and pyæmia is probably connected with the large proportion of patients who come to London for treatment in hospitals and other institutions. It cannot be taken as showing any excess of septic microbes in London, much less any inefficiency in antisepsis on the part of London surgeons. The lower rate for puerperal fever in London, as contrasted with the higher rate for the other septic diseases, is satisfactory for obstetric practice in London. The death-rate in England and Wales

FIG. 3.



P. F., Puerperal fever. E., Erysipelas. Sep., Septicæmia and pyæmia. Sc., Scarlet fever. Rh., Rheumatic fever with rheumatism of the heart. Ra., Rainfall at Greenwich. The continuous lines denote the weekly mortality in 1893. The dotted lines denote the mean weekly mortality of the ten years 1883–1892. The numbers have been adjusted by Bloxam's method for the construction of the curves, and reduced to percentages above and below the mean.

appears to be raised by that of remote country districts where medical aid is difficult to obtain and uninstructed midwives are more employed.

The curve of mortality for puerperal fever (Figs. 1 and 2) shows a decided downward tendency, like that of the other four diseases, and this is the more satisfactory since no decided tendency of the kind was shown for any of them in Dr. Longstaff's diagram for the preceding 25 years. It begins at 16 per cent. above the mean for England and Wales and 40 per cent. for London. It finishes at 22 per cent. below the mean for England and Wales and 50 per cent. for London, the lowest point reached. This last result, however, was attained in 1900, for which year the figures for England and Wales are not yet available. Since 1888 it has never been above the mean except for the remarkable rise beginning in 1892 and culminating in 1893, which is more or less common to all the curves but especially marked in puerperal fever, in erysipelas, and, in London, in scarlet fever. Its relation to the exceptionally dry early summer quarter has already been noted. In puerperal fever the rise is more marked in London, where it reached 44 per cent. above the mean, as compared with 34 per cent. for England and Wales.

Since it was formerly a controverted question whether puerperal septicæmia is ever epidemic it is of interest to note that its degree of variation is fairly comparable with that of the other four diseases. It is considerably less than that of scarlet fever, reaching only 44 per cent. above the mean in London, as compared with 108 per cent. for scarlet fever. It is somewhat less than that of erysipelas and septicæmia but decidedly greater than that of rheumatic fever, which for England and Wales does not rise more than 20 per cent. above the mean, though in London in the notable year 1893 it rose 38 per cent. above the mean. The mean death-rate for puerperal fever is greater than in the preceding 25 years—75 as compared with 63 per million living, but this appears to depend, partly at any rate, upon a change in the practice of the Registrar-General. Since 1881 it has been the custom, when any woman's death is returned as due to septicæmia or peritonitis, to send a letter to the certifying practitioner inquiring whether there has been recent parturition. In the first year of this practice 14 per cent. of deaths were added in consequence to the heading of puerperal fever. The numbers, therefore, are strictly comparable throughout the years recorded in my tables but not with previous years.

As regards the curve of erysipelas its most marked feature is its close resemblance, almost amounting to identity, to the curve of puerperal fever. Almost every deviation in the one is represented in the other, except that a small secondary maximum, which in erysipelas occurred in 1882, is deferred to 1883 for puerperal fever, both in London and in England and Wales. Further, in those respects in which the curve of erysipelas for London differs from the curve for England and Wales, it is followed by the curve of puerperal fever for London, so that the latter corresponds much more closely to the curve of erysipelas for London than to the curve of puerperal fever for England and Wales. I would note especially the extra height of the great maximum in 1893 and the pointed instead of square shape of the rise in 1887–88. On the other hand, when the curve of puerperal fever is compared with that of septicæmia and pyæmia, although there is a general resemblance and most of the elevations and depressions correspond, there is a less close resemblance between the relative height of the maxima, as may be noted especially in those from 1888 to 1893. In these respects the curves for septicæmia and pyæmia for England and Wales agree together and differ from the corresponding curves for puerperal fever. The chief difference between the curves of erysipelas and puerperal fever is that the general downward tendency is less in the latter for England and Wales. In London this is only the case up to the year 1886; and afterwards up to the last year recorded the improvement is slightly greater in puerperal fever. A still more remarkable proof of the close relation of erysipelas to puerperal fever will be found in comparing the curves of weekly variations shown in Fig. 3. Not only is the mean curve for 10 years practically identical for the two diseases; but the same is true of the very complicated curve showing the weekly variations in 1893. Every cusp and turn and every date when the curves cross the mean correspond. Even the amplitude is similar, the only difference being that erysipelas varies a very little more widely both in the mean curve and that for 1893. This identity becomes even more striking if the curves are compared with the totally different curve of septicæmia and pyæmia. This resemblance of the curves confirms the evidence of bacteriology as to the close connexion between puerperal fever and erysipelas. I think, indeed, that the inference may be carried somewhat further and that it may be concluded that a variety of streptococcus closely allied to that of erysipelas is more generally concerned in fatal puerperal fever than in other forms of septicæmia and pyæmia, and that the contagion of erysipelas is more dangerous to the puerperal woman than that of any other septic disease other than puerperal fever itself. Associated with the general descent of the curve for erysipelas is the fact that the mean death-rate per 1,000,000 living is only 54 for England and Wales, as compared with 92 for the previous 25 years, during which no decided downward course was manifest. The curve begins for England and Wales at 55 per cent. above the mean and ends at 52 per cent. below it.

The curve for septicæmia and pyæmia shows a general descent rather less than that of erysipelas, beginning at 65 per cent. above the mean and ending at 24 per cent. below it for England and Wales. In London, however, there is a remarkable rise for 1900 to 35 per cent. above the mean, for which I can offer no explanation. The corresponding figure for England and Wales is not yet available; but the curve shows the moderate rise for 1899 which in London, preceded the much greater one of 1900. The mean weekly curve of septicæmia and pyæmia (Fig. 3) has some notable differences from those of puerperal fever and erysipelas. All have maxima in early November and again in January, but in septicæmia and pyæmia the earlier maximum is the larger, in the other two the latter. Again, septicæmia and pyæmia have a high maximum in April which in the other two is represented only by a slight double elevation. The weekly curve for 1893 shows wide oscillations which may be casual variations due to the absolute number of cases being small.

The curve for scarlet fever (Figs. 1 and 2) shows the most marked descent of all, beginning at 106 per cent. above the mean and ending at 60 per cent. below it. The mean death-rate per million is only 247 for England and Wales, as compared with 854 in the 25 years preceding; and from 1885 onward it is only about 168. The main drop took place in the years 1882–85 and was doubtless due to the isolation of patients in fever hospitals. Up to 1891 there is little resemblance of the curve to the three preceding for England and Wales, but more after that date, all having maxima in 1893 and three of them in 1896, three of them minima in 1895 and all of them minima in 1898. In London the curve for scarlet fever has a somewhat greater resemblance to that of erysipelas and puerperal fever from 1886 onward. The more marked epidemic rises in scarlatinal mortality in the preceding 25 years were not accompanied by serious corresponding rises of puerperal fever nor is the drop of scarlet fever in 1882–1885 associated with any equivalent drop of puerperal fever. The extra maximum of scarlet fever in London in 1887 as compared with England and Wales leads to no similar maximum of puerperal fever, but the curve of that disease has a rise only corresponding to that of erysipelas. The mean weekly curves of puerperal fever and scarlet fever are quite different (Fig. 3), scarlet fever rising slowly to a maximum at the end of October and falling considerably before puerperal fever rises to its main maximum in early January. The diagrams therefore give no support to the view formerly held extensively in England that contagion from scarlet fever is an important cause of puerperal septicæmia. Such similarity as exists in the curves may be explained partly from a similar seasonal influence on different microbes, as by a period of unusual dryness. Again, all would admit that scarlatinal throats may be complicated by streptococci; and that thus a septic infection may be carried from a scarlatinal patient to a puerperal woman. There is a further question whether a year in which streptococci are unusually abundant or easily diffused may not increase the mortality of scarlet fever by causing septic complications; and the same consideration would apply also to rheumatic fever. I have no evidence to offer on this point, but some light might be thrown upon it, in the case of scarlet fever, by comparing the mortality with the number of cases notified. The latter has only very recently been included in the returns.

I have included the curve representing rheumatic fever, including rheumatism with affection of the heart or pericardium (but not chronic valvular disease), as a disease allied to puerperal fever, because in the diagram of Dr. Longstaff for the preceding 25 years "rheumatism of the heart" shows a curve closely resembling that of puerperal fever and erysipelas except that it is steadily ascending. Since 1881 rheumatism with affection of the heart or pericardium has been massed together with rheumatic fever in the Registrar-General's returns and the result is shown in my diagrams. The resemblance to the curves of erysipelas and puerperal fever is much less than under the former arrangement. Up to 1891 it is scarcely visible, as in 1887–88 a depression corresponds to the rises in the other curves for London, but from 1892 onward there are three maxima and two minima correspondent, though only one of them, the maximum of 1893, is well marked in all. The mean death-rate per million living is 88, as compared with 46 in the previous 25 years for rheumatism of the heart only. The diminution of similarity produced by the addition of rheumatic fever seems an argument in favour of the view that fatal heart affection in acute rheumatism is often due to streptococcic complications and that thus rheumatism of the heart is more closely allied to septic affections than rheumatic fever in general The curve shows less with variation than the others, but its general tendency is downward, though the improvement is less marked than in the other diseases. What improvement has occurred must be ascribed to general hygienic measures or improved treatment, since precautions against sepsis or infection can scarcely have any scope here. The mean weekly curve of rheumatic fever (Fig 3) has some resemblance to that of erysipelas or puerperal fever Both have maxima in early November and again in early January, but in rheumatism the former is somewhat greater instead of the latter. Both show slight rises in April and in late August and have their minima near midsummer

In conclusion, I think that among the practical inferences to be drawn from the diagrams are the following: 1. That while a satisfactory improvement in the mortality of puerperal fever has occurred for the first time within the last 20 years, a further development of antiseptic midwifery is still required in England and Wales outside London to make the improvement equal to that already attained in other septic diseases. 2. That the relation of fatal puerperal fever to erysipelas is still closer than has been generally supposed, and much closer than that of either disease to septicæmia and pyæmia generally. A consequence of this seems to be that an anti-streptococcic serum derived from erysipelas would be more likely to be useful in puerperal fever than one derived from any other source of streptococci except puerperal fever itself.

An Address

ON

THE TREATMENT OF PULMONARY TUBERCULOSIS BY HYGIENE.

Delivered before the Cardiff Medical Society on May 29th, 1902,

BY C. THEODORE WILLIAMS, M.A. OXON., M.D., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

MR. PRESIDENT AND GENTLEMEN,—The subject which I have chosen for my address is perhaps the one most largely discussed by the medical profession and laity at the present moment and it may be said to interest all classes of the community from the highest to the lowest. My object in choosing this topic is to offer to you some thoughts and reflections arrived at after a considerable experience in the treatment of tuberculosis by hygiene and especially to indicate the best methods of applying this treatment. What I mean by treatment by hygiene is what is usually termed open-air treatment, but I prefer the former title as more comprehensive and, indeed, more correct, and I thus distinguish it from medicinal and climatic treatment

Hygienic treatment was probably first systematically practised by Mr George Bodington of Sutton Coldfield, Warwickshire, whose *régime* for consumptives was admirable and apparently very successful, though either from being insufficiently known or unpalatable it does not seem to have been largely adopted at the time. Later Brehmer founded the first sanatorium for consumptives at Görbersdorf in Silesia, and introduced his system of graduated exercises in the way of walking in combination with regulated foods and an open air life. Brehmer's reason for introducing graduated ascents was that he believed phthisis to be caused by a small heart which he thought might become more developed by such exercises. His views on the etiology of phthisis generally were remarkable. He held that at the bottom of the mischief was the want of food or a small appetite, and that this led to malnutrition, especially of the heart, which was accompanied by an enlargement of the lungs, and that this want of proportion between the heart and the lungs was the true predisposing cause of phthisis Brehmer lived long enough to recognise the actual cause of tuberculosis in the tubercle bacillus, but to the end of his life he insisted on the prominent part played by the small heart and the importance of increasing its dimensions by exercise. This was a mistake on his part, as the small heart is due to that wasting of the organs and tissues which affects the body generally in phthisis and is the result, and not the cause, of the disease. Another point which Brehmer insisted on was that the places chosen for the treatment of consumption should be immune from the disease and he dwelt on the importance of altitude in this respect. But since his time we have learnt a good many lessons about immunity, and one is that sparseness of population has much to say to it and that the prevalence of tubercle depends largely on the density of population. But in spite of all this Brehmer's practice was excellent and he was able to show very satisfactory results Dettweiler, his disciple, carried on his treatment but diminished the amount of exercise and introduced the rest cure, in which patients pass the greater part of the day on couches in the open air, properly protected from rain and wind in *liege-halles* or shelters. This is the system most in vogue in Germany now and it is especially adapted to febrile and advanced cases. Walther at Nordrach modified this system again and claims that he follows more closely in the steps of Brehmer, the chief features of his *régime* being (1) graduated exercise in all sorts of weather and indifference to wet and cold, (2) rest in bed or on the sofa at stated hours and always in the solitude of the bedroom and not in the society of the *liegehalle*; and (3) forced feeding with highly nutritious food three times a day Both these methods combine open-air treatment with a certain amount of stuffing and the great difference between them lies in the quantity of exercise prescribed and of the social intercourse permitted. In both systems careful observation and regulation of every detail of the patient's life are inculcated and it may at once be stated that both systems show a large measure of success

One of the great advantages of the open-air treatment is that it is suited not only to cases of early and limited pulmonary tuberculosis which can be arrested by various measures, but that its benefits are also well shown in cases of extensive tuberculisation with cavities, irritable or quiescent, and above all in pyrexial cases, where owing to the pulmonary changes the pyrexia is often very persistent. In such patients, after all the antipyretics, pharmacopœial and extra-pharmacopœial, have been exhausted, it is found that exposure on a bed or on a light couch by day and by night to the pure air in a shelter or verandah will in time prove effective and the pyrexia will gradually subside. How fresh air of a low temperature affects the thermotaxic and thermogenic nerve centres and thus reduces fever it is not easy to say—whether by soothing the nerve centres or by stimulating and finally exhausting the combustive process I cannot tell, but the fact I have noted in many instances I have known patients with active tuberculous disease accompanied by afternoon pyrexia which had lasted for months placed on couches in shelters and I have observed that in most of these cases the pyrexia has subsided after some weeks in the open air Many of these patients were not in sanatoriums but in their own gardens under the superintendence of a medical man or a nurse. The open air life, whether in an institution or in a private house, at first, and especially in pyrexial cases, causes a feeling of chilliness, but this soon passes off with proper clothing and particularly if the invalid remains in the prone position with the head and thorax sufficiently raised to render expectoration easy. Patients who are chilly in the sitting position can stand an extraordinarily low temperature in the lying position from its more equalising effect on the circulation. Of course, in this treatment draughts, and as much as possible wind, must be avoided, but with suitable windows and well-constructed *liegehalles*, or revolving shelters, these may be successfully guarded against.

The open-air system has been in use at the Brompton Hospital for some months and is very popular with the patients, who come for the most part from the labouring classes, and I noted last winter that whereas they used always to sit round the fire to read their newspapers and books they now prefer places near the open windows. In carrying out this treatment we should remember that pyrexia should at first be treated by the patient lying in bed with open windows and, if the temperature does not fall, that the bed should be moved on to a terrace or covered balcony protected from rain but freely open to the air. If the temperature falls, the patient can be transferred to a couch and in time to the *liegehalle*.

Food.—The dietary is a very abundant one and constant supervision is required to ensure the full amount of food being taken, in spite ofttimes of a failing appetite. All classes of food should be represented—the nitrogenous, the fatty, and the carbohydrate groups—in proper ratios. Some sanatoriums give three square meals a day and allow of no intermediates and in others intermediate meals of milk, bread, butter, cheese, and jam are encouraged in the forenoon and afternoon. In all cases milk is consumed in quantities of from three to five pints a day and butcher's meat with abundant vegetables, and especially potatoes, twice and in some cases three times a day. In most of the sanatoriums the appetite has ceased to be the guide of life and in those of the Nordrach type cramming is carried on even in some cases to the extent of producing vomiting. Most of the patients manage to retain their large meals but occasionally one has to retire from the festive board and on returning somewhat pallid finds an inexorable medical attendant and the plateful has to be finished all the same.

A curious feature is that in highly pyrexial phthisis the digestion of both nitrogen and fats is good, as is shown by Dr. F. W. Goodbody, Dr. N. D. Bardswell, and Mr. J. E. Chapman,[1] for they found that quantities of food which produced illness in ordinary individuals have a favourable effect on consumptives. They observed, too, that even when the patients were far below their normal weight better results were obtained by moderately large diets than by very large diets, and it would appear that by "medium diets one obtained the maximum of absorption and the minimum of amount of labour." So that we may conclude that pushing feeding to the vomiting point is neither judicious nor profitable and that better results may be looked for from more moderate dietaries. The absorption of fats by consumptives is excellent It was observed that when as much as 231·32 grammes were given 96·41 per cent. were absorbed. Food has to be diminished as the disease becomes quiescent and the patient approaches normal weight. It is one thing, however, to fatten a patient and another thing to give him strength and muscle, and it must be admitted that in many cases the gain of weight is more in fat than in anything else—fat which often disappears again after the stuffing ceases, and whilst present in such large quantities greatly impedes the patient's movements and makes him short-breathed. I had an instance of this only the other day. An old consumptive patient of mine entered a sanatorium in this country which had a reputation for good food and after about nine months emerged two stones heavier but hardly able to walk uphill and very short-breathed and puffy. He went to Nordrach, and Dr. Walther pronounced him too fat and put him on graduated exercises. At the end of four months he had lost 10 pounds but could walk five miles and his breathing power had greatly improved. Observation of sanatorium feeding makes one sometimes doubt the existence of the dyspepsia of phthisis, for apart from the quantities of food consumed, which, however, it must be admitted, is plain and well-cooked, the mixtures of drinks are often rather trying to digestion. At Nordrach the patients have the option of taking either wine or beer with their meals, but are obliged to drink a stated amount of milk at the same time, and this curious and weird mixture does not seem to upset their digestion, for they swill down two glasses of milk with the meat and vegetables, and then curdle the mass in their stomachs by mixing it with beer or wine. Truly the abundance of fresh air and exercise works wonders.

Rest and exercise.—The relative proportion of rest and exercise and the kind of exercise prescribed have to be carefully regulated from time to time and suited to the individual and this is one of the principal duties of the sanatorium physician. Let us consider rest first. One excellent rule of all sanatoriums is to insist on one hour's rest before both the midday and evening meals so that the patient may approach the meal not jaded but rested after the walk. We all know by experience the effect of muscular fatigue both on appetite and digestion and it is highly important that a patient should come to the meals with his powers of digestion and assimilation unimpaired. The question of the length of time to be spent in the shelters or *liegehallen* depends on the patient's condition. In cases where any fever is present the patient, when not in bed, spends his whole day in the *liegehalle*, but when the pyrexia has entirely ceased from three to eight or 10 hours are passed there daily. As the nervous and muscular forces increase exercise is introduced and often a course of massage with some hydro-therapeutics or the practice of resisted movements in the recumbent position, are a good prelude to walking exercise, but the principle of rest must never be lost sight of and when the patient is not taking exercise he should be resting in the open air.

The form of exercise most in vogue in sanatoriums is walking, first on the level and next on well-graduated ascents, care always being taken that the ascent, if a long one, should be at the commencement of the walk when the patient is fresh and the descent at the end when he may be getting tired. All sanatoriums should have near them well-graduated walks provided with plenty of seats, so that the inmates may have opportunities of resting. Pine woods are excellent for walking in, as they combine shade from sun and shelter from rain and are useful in winter as well as in summer, which cannot be said of woods of deciduous trees. It is remarkable how consumptives by such graduated walking slowly gain strength and breath and from being so short-breathed that they can only walk half a mile and that, perhaps, with difficulty, by degrees can compass five or even 10 miles and that with comfort. The great point is at first not to attempt a rate of over one and a half or two miles an hour and not to hurry to increase the pace, and a clear sign of over-exertion is the meals not being relished after the walk. In most sanatoriums two walks a day of moderate length are taken, but in some four short walks are preferred. It is not advisable, however, to restrict all patients to walking exercise alone, for to many it is very monotonous and ofttimes a fatiguing exercise, and after all brings into action only a limited number of muscles. Riding, skating, cycling, lawn-tennis, croquet, and, above all, golf, which entails a great deal of walking, may be preferred in some cases.

Sanatorium buildings.—I will now say a few words on the position and structure of sanatoriums and their internal arrangements. Undoubtedly the finest sanatoriums are in Germany where there are two kinds, one for the upper classes in which splendid buildings are installed with a certain amount of luxury, and the second for the working-classes, built by, or under the auspices of, the German insurance societies, in which only the essentials of hygienic treatment are aimed at.

The sanatorium should be placed on gently sloping ground well sheltered to the north and east from cold winds, with a sunny exposure, and for this reason and to avoid damp an elevated site is to be preferred. It should be surrounded by extensive grounds, partly wooded, with fragrant pine groves providing dry shelter and permitting exercise in all weathers, and partly with open spaces which should be carpeted, not with rank grass, but with the crisp herbage of the mountain side, abounding in thyme and other sweet-scented plants. It is not desirable to have many roads from which dust may arise, but plenty of well-planned paths through the woods and over the commons. The soil must be dry and permeable so as to facilitate surface drainage, and the water-supply must be abundant and irreproachable. A farm for milk and poultry is advisable. The erection should face due south and stand on a wide plateau. It should consist of at least three buildings—viz.: (1) the sanatorium proper; (2) the medical superintendent's house, which may also contain the consulting rooms and accommodation for other members of the resident staff; and (3) the administrative block, for the motors, electric light plant, and the laundry and disinfecting apparatus, all of which it is as well not to have near the patients' dwelling-place. The sanatorium proper, if 100 or more patients are to be housed, should be of three or four storeys, the south side of the ground floor being devoted to the *liegehallen* unless it is preferred to extend these in wings from each angle of the building. The northern side or wings should contain the dining-rooms, kitchens, and offices and the other sitting-rooms required for patients should be on the ground floor to the south, keeping the whole of the south frontage of the first and second floors for single bedrooms for the patients, which must be lofty with large windows opening in the French casement fashion on to balconies in which the beds can be run out if required, and a tent may also be arranged from above to protect the feverish patient from sun and wind and rain. The upper portion of the windows should open by louvres and all windows should be furnished with wooden jalousie shutters or blinds. In the interior of the sanatorium everything should be arranged to prevent any accumulation of dust and micro-organisms. The floors should be made of teak or planks covered with plaster-of-Paris and this again with linoleum. All corners, whether in rooms, passages, or staircases, and in furniture, should be bevelled and rounded off, and any cracks between walls and floors filled in with wooden wedges or strips of linen painted over with white enamel. The walls of the rooms should be painted or covered with antiseptic washable paper and cleanliness everywhere rigidly maintained. No carpets, curtains, or hangings are advisable. The sputum should be received into Dettweiler's flasks, containing an antiseptic if the patient be out of doors and when it is not convenient to use the spittoons which contain sawdust and are constantly emptied and the contents burnt. The sanatorium should possess adequate disinfecting apparatus for clothes, cushions, and bedding and a destructor for the sputum. The system of drainage should be complete and in perfect order. Heating in winter is satisfactorily accomplished by radiators and electric heating has been tried with success.

---

[1] Vide an admirable paper in vol. lxxxiv. of the Transactions of the Royal Medical and Chirurgical Society.

There should be two sets of *liegehallen* for winter and for summer, the winter one with southern exposure and the summer one facing north in the woodland. The walls of these should be lofty and the shelters spacious with well-fitting blinds in front to afford protection from sun and storm, but open enough to allow of abundance of air at all times. They should be furnished with light bamboo couches covered with mattress and with cushions of horsehair for the patients to recline on, and there should be lockers and tables for books and papers and games and an electric light by each couch. Finally, at the head of the sanatorium should be placed a medical man of decided views, of strong common sense and power of discrimination, and with a large knowledge of human nature, endowed with an inflexible will but possessing a sweet temper and ready sympathy with disease and especially with its chronic manifestations.

In all systems there are some elements which are more essential than others and it seems to me that in the open-air system there is no exception to this rule. The most important factor is that of fresh air, both for prevention and arrest of the disease, and the more one trusts to its influence the more one becomes convinced of its wonderful efficacy. We are sometimes, indeed, tempted to hazard the opinion that it would have been well for mankind if our present sort of houses had never been adopted and if we had continued to dwell in tents or in airy sheds. Nomadic tribes dwelling in tents have generally been healthy and at all events free from consumption. Next in importance to fresh air we must reckon the abundant and forced feeding.

Last of all, though by no means to be neglected, are the precautions against possible infection. When we consider the numberless opportunities of infection from the ever-present tubercle bacillus by inhalation through the air-passages or through the stomach by swallowing we must admit either that the bacilli in entering man and animals encounter serious opposition to their settlement and spread or else that a large proportion of the population is immune to their attack. I doubt the latter conclusion because it is found that robust individuals can become liable to tuberculosis after being placed under the depressing conditions of want, bad air, or unwholesome trades. The first conclusion is more likely to be correct for the trachea, the most probable channel of entry for the bacillus tuberculosis, is well protected by a triple layer of epithelium and the lashing movement of the cilia would tend to expel bacilli entering with dust particles. We must not, however, expect too much from the hygienic treatment of consumption. There are forms of phthisis, such as the catarrhal variety, where hygienic treatment fails to accomplish much and where the help of a warm climate and good nursing are necessary for success. But this treatment is one which is well adapted to the majority of cases of lung tuberculosis, and when combined with good climatic conditions like those of high altitudes it certainly tends to accomplish great things.

GOLD MINERS' PHTHISIS AND SOME OF THE DANGERS TO HEALTH INCIDENTAL TO GOLD MINING IN THE TRANSVAAL.

By THOMAS OLIVER, M.A. Durh., M.D. Glasg.,
F.R.C.P. Lond.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE UPON TYNE.

WHILE the war in South Africa has taught us as a nation many things of which we were ignorant as regards methods of warfare and has again impressed upon the War Office the important fact that it is disease and not the bullets of the enemy that is responsible for the larger number of deaths of soldiers engaged on active service, it has at the same time, by having liberated many men who were employed in gold mining on the Rand, given us the opportunity of learning that gold mining, as was previously the case with coal getting in Britain, can be very destructive to human life. To the Transvaal mines there have gone from time to time men from the colliery districts of Northumberland. Some of these men have returned to the North of England only to die from phthisis. During the last two years, owing to the closing of the mines and the continuance of the war, miners have returned here in large numbers, many of whom have presented on their arrival the appearance of men broken down in health and who have sooner or later succumbed to pulmonary disease. It has been my fortune to have been consulted by some of these miners, whose lung affection had assumed the characters of a veritable pulmonary fibrosis. Now that the war is over there will in all probability be a rush of miners once more to South Africa. I feel therefore that if attention can be drawn to the need for something being done to alter and improve the methods of mining in the Transvaal, and to the necessity for revising and strengthening the mining regulations of that country, the loss of many lives of miners may by this means be averted.

Gold miners' disease of the lungs is due to the inhalation of dust; it is therefore a malady akin to stonemasons' and steel grinders' phthisis. Like all the pneumoconioses it is slowly developed. The earliest symptoms are cough, especially in the morning, with a little frothy mucous expectoration which is expelled with difficulty, but once this is got rid of cough in the early stages is not a prominent feature during the rest of the day. What impresses itself most upon the patient as time goes on is an increasing difficulty of breathing; he becomes short-winded on the slightest exertion. So long as he keeps quiet the breathing may be perfectly easy, but he has only to perform some muscular act necessitating a little exertion, or to walk in the face of a cold or strong wind, when the breathing becomes difficult, loud, and noisy, as in asthma, but with none, or next to none, of the audible moist wheezing sounds that are characteristic of asthma associated with chronic bronchitis. There is no complaint of pain in the chest, only a sense of tightness. Hæmoptysis cannot be said to be a symptom of the disease. By degrees the appetite is lost and emaciation becomes slowly progressive. There is no rise of temperature until towards the terminal stage of the illness and even then it may not be very marked. There is a tendency for the pulse to be quickened, but there is none of the night-sweating that is so characteristic of tuberculous phthisis. Even when the illness has existed for several months and the patient has lost several pounds in weight he may yet under the influence of change of air take on the effects of the sun, become bronzed, and assume the appearance of a healthy man. He is, however, unfitted for work, for very slight muscular exertion induces a paroxysm of dyspnœa. The dyspnœa is in the early stages out of all proportion to the amount of lung tissue apparently destroyed. Health is only very gradually lost. The disease which is called by miners in the Transvaal the "gold dust complaint on the lungs" may attack any portion of the lung—apex, mid lobe or base—but it has, like the pneumoconioses generally, less predilection for the apex than has tuberculous phthisis. From first to last it is, practically speaking, an afebrile and a painless affection. Like stonemasons' and steel grinders' phthisis, the malady seems to commence as a peri-bronchitis and is followed by an increase of the fibro-connective tissue of the lung. It resembles these diseases in this respect that subsequently it may have a tuberculous lesion grafted upon it.

PHYSICAL SIGNS.

On percussing the chest of a gold miner who is the subject of this disease there can usually be detected distinct dulness, limited in area but well defined. At this spot, if it is in the front of the chest, the breath sounds are louder and coarser than usual and as the disease progresses dry clicking can be heard towards the end of inspiration. The expiratory murmur is prolonged. Over the back of the chest the respiratory murmur is coarser than in health, dry clicking may also be heard as well as exaggerated vocal resonance. Vocal fremitus may be slightly intensified. The physical signs are those of a limited fibrosis of the lung, unaccompanied for the most part by acute pleurisy, for pain, as already stated, is absent. As the disease proceeds there occurs, if the fibrotic patch is in the upper part of the left lung, considerable retraction of that organ, so that an unusually large area of cardiac pulsation is seen and felt; the closure of the valves at the root of the large vessels springing from the base of the heart is more easily felt, and the apex beat is lifted up an interspace or more. The heart is usually excitable even in the early stages, a circumstance that aggravates the difficulty of breathing. In uncomplicated cases the heart's sounds are healthy, but in consequence of the obstructed circulation through the lung the second sound heard over the pulmonary artery is extremely accentuated. It is not until the disease has lasted a considerable time that there is observed any marked difference in the measurement of the two sides of the chest, and it is not until the terminal stage of the malady is being reached that moist râles are heard to any great extent in the lungs. The attacks of paroxysmal dyspnœa are not accompanied by cyanosis, nor is there anything of an approach to early morning asthmatic seizures, obliging the patient to sit up in bed about 4 A.M., as occur in ordinary asthma. Expectoration is not abundant and although I have carefully searched the sputum for tubercle bacilli these are absent in the early stages of the illness even when the physical signs of pulmonary fibrosis are well marked. Gold miners' phthisis is, therefore, at its inception, like all the other pneumoconioses due to dust-irritation, a non-tuberculous disease. Dr. James Anderson of Seaton Delaval, Northumberland, who has seen several cases of phthisis in gold miners returned from South Africa, informs me that hæmoptysis was not in his patients a marked symptom and when it occurred the blood was present only in very small quantity. The disease, he says, bears "no great similarity to the ordinary form of tubercular phthisis with cavity formation ...... consequently the expectoration is not nearly so profuse as in such cases, nor is the rise of temperature ever very marked."

There is a feeling among the gold miners in the North of England who have returned from the Transvaal that men who are the subjects of the disease in question bear residence at the seaside badly. When the war broke out in South Africa many of the miners made their way from the Rand to Port Elizabeth and other places on the coast of Natal, but it is stated that many of these men died, their health having given way rather rapidly. Some of these miners were not known to have been seriously ill at the time and others had been ill for only three or four months. On inquiry as to the fatal termination of these cases having been possibly hastened by an excessive use of alcohol I am informed that several of the men who thus so rapidly succumbed to the malady at the seaside were total abstainers. So far as I can learn there is nothing in the housing of the miners in the Johannesberg district that throws light upon the development and spread of the disease.

THE DANGERS INCIDENTAL TO GOLD-MINING.

There are two risks to health incurred by the men in the act of mining, also a possible danger in the abstraction of gold from the rock by means of what is known as the "cyanide process." In *mining for gold in South Africa* the same steps have to be gone through as in ordinary coal-mining, &c., at home. A shaft has to be sunk before the auriferous ore can be reached. In sinking a shaft large quantities of high explosives—e.g., dynamite and blasting gelatin—are used. After an explosion the air is fouled, partly by nitrous fumes and partly by the dust given off from the mineral débris. The shafts are sometimes very deep—half a mile or more. The poisoned air, therefore, hangs heavily at the bottom of the shaft where progress is being made and this air is with difficulty cleared. Too soon after the series of explosions has occurred that corresponds to the number of cartridges placed in a shaft in process of construction the miners descend into the polluted atmosphere. After a few respirations of the foul air rich in nitrous fume a miner is occasionally seen by his comrades to fall and to pass into a state of deep sleepiness or narcosis from which he quickly recovers if he is taken to the surface and given ammonia to inhale. The face is pale under these circumstances and there is said to be neither cyanosis nor difficulty of breathing. The miner has simply been poisoned by the fumes. On recovery there is complaint of severe headache, just as after nitro-glycerine, accompanied by distaste for the next meal. Unless the affected miners have been given whisky on coming round there is no vomiting.

The sinking of a shaft at a gold mine is regarded as "wet" work. There is a limit to which the depth of mines can be carried so as to be successful from a financial point of view. The deeper the gold mine the higher is the temperature and the greater is the difficulty of ventilation. The increasing rise of temperature as greater depths are reached is due to the heat of the earth, the methods of working, and the decomposition of mineral substances present in carbonaceous and pyritic shales. While in some instances there has been observed a rise of temperature of 1° F. for every 82 feet descended,[1] in other mines the increment is not so regular as to be capable of being stated in terms of proportion. In some of the rand shafts Mr. A. F. Crosse[2] found at a depth of 825 feet a temperature of 66·7° F. and at 1030 feet 70 7° F. The shafts are vertical when they are sunk to strike the reefs in underlay, or inclined when they follow the inclination of the beds. It is easy to understand, therefore, how very polluted the atmosphere must be at the bottom of a deep vertical shaft. In order to secure adequate ventilation of deep gold-mines the Transvaal mining regulations insist upon two shafts being sunk as in British collieries.

It is in the act of mining and not in that of shafting that the danger of pulmonary disease arises. Gold mining is spoken of as "dry" work compared with the shafting, known as "wet" work. It is a very dusty process and is justly regarded by the miners themselves as a fertile cause of lung disease. The rock is often hard and has to be drilled by machinery worked by compressed air. In using the Ingersoll rock drill very large quantities of dust are given off which the men inhale. It is the dry dust given off in drilling the rock that is the cause of the lung trouble in gold miners. A man may work five or six years before he is rendered *hors de combat* by the dust. Gold miners' phthisis, therefore, kills men when they are still comparatively young, usually before they reach the age of 40 years.

In order to extract the gold the crushed rock is placed in huge zinc vats several yards long and many feet deep, into which a solution of cyanide of potassium is pumped. Potassium cyanide slowly dissolves gold. The zinc of the vat gradually displaces the gold in the cyanide so that the gold is subsequently found in a pure metallic state and in a somewhat spongy form adhering to the sides of the vat. Although cyanide of potassium is a powerful poison there has been a remarkable absence of constitutional poisoning due to it. The liquid, however, is capable of causing irritation and sores of the hands if there are any fissures or cracks on the skin.

TREATMENT.

The attention of mining engineers might be directed with advantage to improving the methods of drilling the rock and of ventilating the shafts. If any good by treatment is to be got at all it can only be by affected gold miners renouncing their work in the very earliest stages of the illness and following outdoor employment. Strength must be maintained; good food and fats are desirable; virol and the various emulsions are worthy of a trial. Fowler's solution with nux vomica and iodide of potassium may be given. Until a larger experience of the disease has been gained it would be better to send the patients for change of air, not to the seaside, but inland to fairly high altitudes—say 700 feet or more above the sea level.

EARLY PERITONITIS.[1]

BY WILLIAM HENRY BATTLE, F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL.

THE importance of recognising the earliest indications of peritonitis due to disease of the appendix can scarcely be exaggerated, for it may make all the difference between life and death to the patient, the condition being capable of arrest and cure in the early stage and only occasionally so in the later. If all cases of peritonitis due to disease of the appendix showed certain general characteristics resultant on their origin, or if they began abruptly in the same way, it would not be necessary to ask your attention to the subject, for descriptions would be printed in every text-book both on medicine and surgery. But it is not so, and in quite a large number peritonitis is insidious in its origin. The question which always presents itself to those in charge of a case presenting symptoms of appendicitis of a mild type is whether it is better to wait or to have recourse to immediate operation. If we can point to any symptom that will enable us to speak authoritatively in answer then we have gained something in our contest against a disease which presents itself under so many forms. Much depends on the reply to this question.

Many of you have seen the subjects of peritonitis brought to the hospital in the last stage of the disease, for there is hardly a week passes without the arrival of one or more of them. You know the appearance of these cases, their symptoms, and the condition of the abdomen. The disease is usually so advanced that one of the first questions put to their friends is, Why was the case not brought up before? and in most instances the reply is that there had been a serious change for the worse and their medical attendant had then advised them to come to the hospital—they had not known the patient was so ill before that. We know that the friends of patients rarely appreciate the severity of an illness, but it is not only that the friends were mistaken, as they might easily have been, but there can be little doubt that their medical attendant was also deceived by the mildness of the symptoms in some of these cases and the only conclusion we can come to is that the disease must have been most insidious. One has seen these cases in private as well as in hospital practice and the experience is always a painful one. The history is the same—symptoms of a mild attack of appendicitis and then a sudden change for the worse, or the rapid development of some unfavourable symptom, generally four or five days after the commencement of the illness. The abdomen is usually found to be distended and there is no movement during respiration excepting in the thoracic region. The abdominal wall is hard, tenderness is general, and on percussion you find a tympanitic note in front with dulness in the flanks, sometimes there is dulness also over the pubes—this dulness is that of fluid and it shifts with the position of the patient. Thrill is rarely found. If the abdomen is opened you let out a large quantity of very offensive purulent fluid and probably find a perforated or diseased appendix; but whatever further measures are taken you seldom save the life of the patient. He has received such a dose of poison that he cannot recover and death, usually from heart failure, soon ensues.

I have dwelt upon the local aspect of the case because I am strongly of opinion that more lives will be saved if we pay closer attention to the exact progress of symptoms as revealed by accurate abdominal examination. If you inquire when the evidence of fluid first showed you will probably get a very uncertain reply. The fact is, that attention has not been drawn to the necessity of looking for intra-peritoneal effusion, nor has its importance been recognised as it should be. Then, again, the experience which some men obtain in abdominal examination during their course at the hospital is, to say the least of it, imperfect, and they are in consequence not always able to appreciate the difference in note which is caused by an early effusion. I often advise students in the wards to examine the abdomen whenever they have opportunity, as also never to miss a chance of trying for fluctuation in any case where it is suspected. Cultivate the sense of touch. You may point out the presence of dulness in the flanks and receive the reply "Yes there is, I see, dulness in the flanks but that is due to a full colon, and the dulness goes from the side which is uppermost because the full colon falls away by its own weight." It is then pointed out that the dulness in the opposite side is increased in extent by the change of position or it may be that the dulness extends across the abdomen above the pubes when the patient is lying on his back. The appearance of the face is very deceptive. The temperature may be normal or subnormal, as you know, in suppurative peritonitis, but when you have to diagnose the condition from the facies Hippocratica, a rapidly failing pulse, and a distended fixed abdomen, the diagnosis is not of much use to the patient. I have for a long time considered that the detection of the presence of effusion in the peritoneum was of great importance in the diagnosis of peritonitis in its early stage and the patients I show you to-day are proofs of the good result of the treatment which has resulted from that conviction. The three patients formerly in the hospital were brought up by their friends in quite an early stage of their trouble. No opium had been given to ease their pain nor had anything been done calculated to alter the course of the illness. They were ill but the parents were not alarmed at their condition and had not called in medical assistance.

The following is the clinical report of the patient I now show you.

CASE 1.[2]—A girl, aged 14 years, living at home, was admitted into St. Thomas's Hospital, under my care, on Dec. 21st, 1900, with the following history. In May of that year she had been operated on by a surgeon at another hospital for peritonitis, and after her recovery from this condition she was sent to a convalescent home at the seaside. She was there taken with pain in the abdomen and an abscess developed which was opened. From this she recovered satisfactorily. She was taken ill again on Dec. 19th with pain in the abdomen and vomiting there being no constipation. On admission the abdomen was found not to be rigid or distended and it moved well on respiration. She complained of pain under the right rectus and also half way between the umbilicus and anterior superior spine. There was evidence of free fluid in the right flank, but no tumour could be felt. She had vomited in the morning, but now the tongue was clean and moist and she did not feel sick. The temperature was 100·2° F. and the pulse was slightly quickened. There was a scar, the result of the first operation, in the middle line below the umbilicus, and another, the result of the second operation, in the right linea semilunaris, over the region of the appendix. Her expression was good and she did not look ill. The incision on this occasion was made over the rectus on the right side of the abdomen and after displacement of that muscle the peritoneum was opened. A quantity of thin pus having a fæcal odour escaped and more was removed with sponges. The appendix was found with some difficulty and removed; it was bound down by old adhesions. It contained a fæcal concretion of the size of a small hazel nut over which there was a perforation. There was a patch of lymph over one part of the ileum but no general dissemination of it. The vessels of the intestine were also unusually distinct but otherwise there was no change in the appearance of the peritoneum. There were *no* adhesions of intestine or omentum. The wound was closed after a careful cleansing of the peritoneum, without drainage. On the 28th, however, when the stitches were removed it was found that a rise of temperature was accounted for by a collection of pus which was discharging through the outermost of the scars and which had a distinctly fæcal odour. Her progress towards recovery was good after this date and she left well on Jan. 24th, 1901. The recent wound had not suppurated.

I was rather inclined to regard the slight symptoms produced by the perforation of the appendix and the effusion in the peritoneum as the result of lessened sensitiveness of the peritoneum as a consequence of the former inflammatory attacks. This was not a correct view, as Cases 2 and 3 will show. You can see that the scars are all of them without weakness; there is no bulging when the abdominal wall is strained, and the girl, who looks well, has had no illness since she left the hospital.

---

[1] Abstract of a clinical lecture delivered at St. Thomas's Hospital.

[2] Vide THE LANCET, Jan. 18th, 1902, p. 145 (Case 5

The history of this second patient is as follows:—

CASE 2.—A youth, aged 15 years, was admitted into George Ward in St. Thomas's Hospital under the care of Dr. H. W. G. Mackenzie on August 2nd, 1901. For about four years the patient had had attacks of pain in the abdomen but had never been kept at home by them for more than two days. He had had about seven or eight attacks altogether; the last one was in the previous March. When returning from work at 6 o'clock in the evening of the day before his admission to the hospital he again felt pain in the abdomen and on arrival home he was unable to eat his supper. He could not sleep and a hot fomentation was applied. In the morning he was a little better and returned to work, but while there he was taken much worse, the pain in the abdomen became very severe, and he was sent up to the hospital in a cab. The patient was a well-nourished lad with flushed cheeks and he complained of pain in the abdomen. On examination the abdomen moved only slightly and in the upper part it was somewhat distended on respiration, and there was general tenderness which was most marked below the umbilicus. The liver dulness was normal. No definite tumour could be made out but there was dulness in the flanks and above the pubes, shifting with position. The chest sounds were normal. The pulse was 112; it was of fair tension and was regular. The tongue was lightly furred but was not dry. The temperature was 100·8° F. The bowels acted the day before admission. I was asked to see the case about 2.30 P.M. I found the patient suffering but little. The expression of the face was good and he smiled pleasantly when answering questions. The pulse was less frequent—about 90—but with the exception of increase in the dulness of the flanks there was little change.

About 18½ hours after the onset of pain the appendix was removed after incision of the rectus sheath with displacement of muscle. On opening the peritoneal cavity free purulent fluid was found which filled the pelvis and extended into both flanks; it resembled thin gruel and was of a dirty yellowish colour, in quantity about a pint or more, and not offensive in odour. There was no lymph. The intestines were not distended, they showed no change in the normal polish, and the only thing unusual was a dilatation of the vessels in the walls of the gut. The appendix after removal was about two inches in length; the last inch was intensely inflamed and contained a few drops of pus. At one spot near the tip the wall was extremely thin, evidently being on the point of perforation. The rest of the appendix towards the cæcum was pale and thickened and contained a stercolith. The peritoneum was sutured over the stump of the appendix, after which the peritoneal cavity was washed out with saline fluid at a temperature of 105° F. A glass drainage-tube was passed into the pelvis. The pulse and temperature gradually fell to normal on the fourth day and as the amount of discharge from the tube was slight it was removed on the sixth day, the stitches being removed on the seventh day. The patient made a rapid recovery and left the hospital on August 20th.

The account of the third patient is very similar to that of the patient in Case 2.

CASE 3.—A boy, aged nine years, was admitted into the Leopold Ward of St. Thomas's Hospital on Oct. 10th, 1901. Some months before the patient had pain in the abdomen and vomiting, but the pain was in the upper part of the abdomen and passed away in a few hours. On the afternoon of the 9th when in school the patient had an attack of pain in the upper part of the abdomen. He went home, when he vomited once. He complained of a smarting feeling and pain lower down on the right side of his abdomen. On the next morning the patient vomited again and his mother brought him up to the hospital in the evening. When admitted his temperature was 101·6° F. and the pulse was quickened—from 70 to 80—but the boy did not appear ill. On examination of the abdomen there was found to be some slight distension but the walls moved well with respiration. Examination with the hand was well tolerated, and the patient did not complain of any pain excepting on pressure to the right of the umbilicus, and then he did not complain much. The right rectus in this region was rather rigid. No tumour could be felt but on percussion there was evidence of free fluid in the pelvis and the right flank. The symptoms were altogether obscure but it was thought best to explore the affected region, the free fluid being regarded as an unfavourable sign.

Operation was performed at 9 P.M. An incision was made through the right rectus muscle and the peritoneum was opened. A quantity of yellowish-white fluid, which was not offensive in odour, at once escaped from the opening and a quantity (from six to seven ounces) was sponged away from the pelvis and outer side of the ascending colon and cæcum. The appendix was lying to the outer side of the cæcum, slightly bound down and curled on itself. It was six inches long and contained a concretion over which there was a perforated ulcer. The appendix was removed in the usual manner and the peritoneum was cleansed with warm saline. A Keith's tube was inserted and a gauze plug placed beside the tube. The peritoneum, the rectus, and the aponeurosis were stitched with silk, while fish-gut was employed for the superficial sutures. No lymph could be seen anywhere, not even about the cæcum; the intestine was not sticky and the only visible change was an unusual distinctness of the vessels in the intestinal walls. The temperature became normal by the 14th. There was no more vomiting or pain. The discharge was slight, so the tube was removed on the 12th. The gauze plug had been taken out on the previous day. The wound was somewhat slow in healing but he was quite well and able to go home on Nov. 12th.

Additional proof of the importance of early recognition of this symptom is afforded by the following case. It resembles the others very closely although the patient was older. Luckily for her she was under skilled observation and her condition was recognised at once and promptly treated.

CASE 4.—The patient was a nurse; she awoke at 1 A.M. on the night of April 30th, 1902, complaining of pain in the abdomen and she was sick. There was at this time no rise of temperature and a dose of castor-oil was given for the relief of the supposed colic. She had been perfectly well the day before and engaged in the wards of the institution in which she was employed. As the day progressed she had continued paroxysms of pain, especially in the right iliac fossa, and about midday the temperature rose to 102° F. It fell towards evening but the pain continued although the bowels were well acted on by the medicine. In the temporary absence of Dr. Donaldson Dr. W. M. Jackson asked Dr. F. Bryan to see her. He agreed that the patient had peritonitis and I was asked to go down. The patient was a young woman, about 24 years of age, pleasant looking, and without the abdominalis facies. She was lying on her back, had a somewhat rapid, thoracic respiration with slight working of the nostrils, and a pulse of 120, which, however, quieted down. The tongue was moist and not particularly furred. Examination of the abdomen showed little movement with respiration. There was a long red firm scar running across from the right kidney region with a curve into the iliac region which was said to have been made at an operation in December, 1901, when she had some disease of the appendix. There was tenderness with some rigidity of muscles, especially in the right iliac region, but tenderness and pain also troubled her on the left side, whilst the tenderness was to some extent general. There was some shifting dulness in the flanks but not above the pubes. When the patient was under chloroform, which was administered by Dr. W. J. Thomas, some thickening was felt in the region of the appendix, but it was a question whether this process had already been removed or not at the former operation. Anyway, the scar resembled that of the incision suggested by Dr. J. R. Morison for this purpose when pus is present. The patient did not know: all that she was able to say on the subject was that the gentleman who operated would be pleased to answer any questions as to what had been done. I thought that this indicated a failure in the attempt to remove the appendix.

An incision was made through the right rectus muscle and on opening the peritoneal cavity pus of an offensive odour came from the region of the right iliac fossa and right kidney. It was thin, a kind of brownish sero-pus, and several ounces came away during the progress of the operation; there was some both in the pelvis (where there were old intestinal adhesions) and in the right flank. The ileum and the cæcum were partly coated with lymph, which was irregularly but not widely [illegible]ied, and there were some flakes on the bowel towards the middle line and pelvis but in no great quantity. The appendix could not be found at first and a fleshy projection near the caput cæci resembling a stump made it appear possible that it had been removed. However, the impression that this was a mistake remained and further search was made. There was no indication of its presence in the iliac fossa, for the peritoneal surface appeared continuous and there was no undue hardness to be felt. For some time it could not be found but finally towards the pelvis a slight bulging which proved to be the apex of the appendix was discovered and the finger carried along it freed it, with some difficulty, from its bed of adhesions and after ligature of its mesentery it was removed, a second ligature being applied to its proximal end. The stump was not invaginated but its mucous surface was sterilised with a drop of pure carbolic acid. The abdomen was then washed out with gauze sponges in holders and the wound was closed, a glass drain being passed into the pelvis. The appendix was the subject of a chronic catarrhal inflammation and presented a large perforation where a portion of the wall had sloughed which easily admitted the finger-tip The tube was removed on the third day but discharge continued for some time from the wound The patient made a satisfactory recovery I may say that the scar resulting from the former operation is a very good one and without any sign of weakness.

The note of Dr Mackay, for which I am indebted to him, was to the effect that the patient had had an attack of peritonitis at Christmas time. At the outset appendicitis could not be diagnosed; with the clearing of distension and effusion, however, Dr. Mackay made out a tumour in the right flank which soon showed signs of deep fluctuation. He suspected peri appendical suppuration and operated, hoping to find an easily removeable appendix. Some foul pus was evacuated but the appendix could not be found without breaking down the adhesions of the abscess cavity and therefore he had to leave it.

This case is a further confirmation of my contention as put forward in a recent paper that the appendix should be excised in the quiet period, if for some reason it is not removed when an abscess dependent on its disease is opened. Experience of other cases since that statement was written has strengthened my feeling on this question.

We have here a group of four cases which presented symptoms of a mild character varying but slightly. Each patient was seized with abdominal pain and each vomited and had a moderate elevation of temperature—in no case was it registered as above 102° F. before operation. The pulse did not in any instance (except in Case 4) exceed 110 when I saw it, nor was the expression of any patient indicative of serious abdominal trouble. Yet in each case there was purulent peritoneal exudation of considerable amount within a few hours of the commencement of the illness and in three of them there was perforation of the appendix, and in the fourth acute inflammation of that structure, with a purulent collection inside it. In all these cases the mildness of the symptoms in spite of the serious condition of the appendix is striking. Inflammation of the peritoneum had already commenced and it is unlikely that it would have become localised

I think that it is very probable that many cases of septic peritonitis have passed through the stage as described in these notes for the patients only to die a few days later because its importance was unrecognised and operative treatment was postponed or neglected. I regard this early effusion as an indication for immediate operation.

Harley-street, W.

THE RELATION OF MENTAL SYMPTOMS TO BODILY DISEASE.[1]

BY NATHAN RAW, M.D DURH., M.R.C.P. LOND.,
F.R.S EDIN.,
PHYSICIAN TO THE MILL ROAD INFIRMARY, LIVERPOOL.

THE relation of mental symptoms to bodily disease is a subject of the greatest importance and interest to us all as practitioners of medicine. It would be impossible for me in one paper to deal with such a comprehensive subject at all adequately, so that I do not propose to speak of actual insanities either as occurring in the course of numerous diseases or as caused by them, but to restrict myself to those temporary mental disturbances observed in association with lesions of various viscera.

Maudsley has said in his "Pathology of Mind" that "it is impossible to be out of sorts physically without being out of sorts mentally," and this we must all admit to be to a great extent true, for our mental well-being depends on the physiological condition of our internal organs, more especially the digestive apparatus, and it is our common experience to observe serious mental disturbance follow visceral disorder We are all acquainted with the "livery" man, in what varying moods we may find him at different periods—at one time so irritable as to be approached only with caution and at another so depressed and dull as by preference to be avoided.

In spite of the importance of the subject very little has been written upon it. A few papers dealing with the mental symptoms in individual diseases have been published but as far as I know no general classification or orderly arrangement of them has been made. My own conclusions are based on an observation of a very large number of insane patients in three large county asylums and also about 26,000 ordinary hospital cases. From this very large clinical field of observation I have had exceptional opportunities of seeing almost every form of mental disorder, temporary and permanent, arising during the course of, or following, serious bodily disease and injury.

One of the most interesting forms of mental disorder is that occurring in visceral disease and which has been so well investigated and described by Henry Head in two papers—the first published in *Brain* in 1893 and the last in the same journal in 1902. The latter excellent and scholarly paper has just been published and I am greatly indebted to it in writing my own paper Adopting the classification of Head we find that mental changes may be produced in the following ways. 1. The circulation to the brain may be so altered either by a disturbed activity of the heart or by the altered condition of the blood. The delirium that accompanies a failing heart may be instanced as an example of a mental change dependent directly on altered vascular conditions 2. Some secretory organ may be attacked by disease, such as the thyroid. In exophthalmic goitre we have evidences of thyroidism with great nervousness and irritability, whilst in myxœdema we have the opposite mental state of depression and hebetude. 3. Disease of excretory organs may lead to the retention of toxic agents in the blood, as, for example, uræmia and jaundice. 4 Poisons circulating in the blood, such as alcohol, may in certain lowered conditions of the body due to visceral disease produce mental changes. 5 "Visceral disease may so lower the patient's resistance that some inherent mental tendency may become manifest as active mental disease." These are the causes of the direct mental effects in visceral diseases and are easily understood, but there are certain diseases of the internal organs which are now known to be accompanied by superficial tenderness of the scalp, the face, and the body, together with radiating pains of the trunk. The pain and tenderness are due to changes in some part of the central sympathetic system caused by disturbance of the internal organ to which sensory sympathetic nerves are supplied. *Head* calls these "reflected visceral pains" and the mental symptoms are indirect for they are associated with visceral disturbances through the mediation of the sympathetic system. We are all familiar with the young anæmic woman with pain in the chest and side, or even with all sorts of patients who complain of tenderness and radiating pains round the trunk and the head, pains which cause much physical and mental distress and which in many cases are accompanied by changes in consciousness. These changes mostly take the form of hallucinations of sight, hearing, and smell and are generally of a temporary nature, disappearing with the disease, but more pronounced mental changes may manifest themselves in the form of varying moods of exaltation, depression, or suspicion. In these moods a patient may have all the symptoms of an insane person for the time being with delusions, but they are in no sense fixed delusions and often disappear as rapidly as they came. The diseases in which these curious mental states are observed are chiefly those of the heart, the lungs, and the stomach, and it is extraordinary in how many cases they will be found in a greater or lesser degree if carefully looked for. It would be impossible in this short paper to enter at all fully into the details of numerous cases of which I have notes, so that I will content myself by describing in a general way the mental state of groups of cases.

---

[1] A paper read before the Liverpool Medical Institution on Feb 13th, 1902.

In phthisis pulmonalis the mental symptoms are often very pronounced and they play an important part in the progress and treatment of the disease. The condition generally known as the "spes phthisica" is not, in my experience, commonly seen and is then seen only in those patients who are not aware of the true nature of their affliction. It is common knowledge that many patients attacked by phthisis suffer very little physical pain and inconvenience—in fact, in very advanced cases except for the cough and expectoration they feel fairly well. It is in these cases where the patient has no idea of the terrible nature of his disease and where a cheerful disposition is preserved that this abnormal hope is described. In my experience the very opposite mental state is often present and in the later stages of phthisis depression, fits of moodiness, with irritability of temper and even delusions of suspicion and fear, are not uncommon. In many cases of phthisis there are intense pain and tenderness over the cervical and dorsal areas with superficial tenderness of the scalp, the forehead, and the neck—reflected visceral pains. In some of these hallucinations of vision are present. A patient will tell you that he has seen a dark figure like a ghost at the foot of his bed in the night which disappears and reappears at intervals. In other cases the patient may develop hallucinations of hearing such as "tapping on the wall," voices from the ceiling, or whispers in his ear. Delusions of suspicion and persecution are sometimes noticed and the patient may think that he is being followed or shadowed and that some impending calamity is upon him. I have observed a few cases in which these delusions have entirely disappeared on the arrest of the phthisis and have not again appeared.

In cardiac disease reflected pain chiefly over the left side of the chest, accompanied by superficial tenderness, is common. This pain is generally over the fifth to the ninth dorsal areas, with tenderness of the forehead, the temples, and the vertex of both sides. The patient may suddenly develop hallucinations of smell and will tell you that the food is tainted and that he has a taste of poison in his mouth and on that account will refuse all food. In other cases there is wild delirium or exaltation of feelings with a sense of great physical strength and anxiety to do hard work.

These mental states are more often present during failing compensation and I have frequently seen them entirely pass away with improvement of the patient's physical condition. All these mental symptoms have up to the present been described and classified as hysteria and hypochondriasis, and it is quite a common thing in making one's visit to the wards for the sister to say that so-and-so has been a little hysterical during the night, perhaps screaming out through fear or saying she has seen ghosts or visions.

I do not pretend for a moment to be able to offer any theory on the association of these curious mental states with reflected visceral pain; that they are frequently present is beyond all doubt and it behoves the physician to be on his guard when they appear lest his patient should be treated either as hysterical or as a lunatic instead of as one who is exhibiting mental symptoms requiring sympathy and care. The conclusions of Head are of interest. Under normal conditions the functions of the viscera are outside consciousness—that is, the heart, the lungs, and the stomach, &c., carry on their physiological duties in health without our conscious knowledge. "But a complete change takes place when reflected pains of visceral origin come into existence. These sensations produced by abnormal activity of the viscera crowd into consciousness and usurp the central field of attention. The patient's character appears to be altered. He will become moody, at one time unduly exalted, at another depressed without cause. Reason is displaced and he will have lost control over the expression of his emotions and of his temper." Head concludes his paper in these words: "When the mental states mentioned above appear in consciousness they seem an intrusion from without, an inexplicable obsession that can neither be controlled nor subjected to logical analysis. All such states have since the earliest times been classified as hysteria and I shall be satisfied if I have been successful in relegating to their proper position a small band of symptoms included under that vast and heterogeneous group."

Heart disease.—I have briefly mentioned before the mental symptoms occasionally seen in heart disease associated with reflected visceral pain, but there is a definite train of mental symptoms often associated with valvular lesions, more especially aortic, and also aneurysms. Some writers describe cardiac insanity as a distinct variety of insanity. These mental symptoms, in my experience, are generally observed towards the close of the disease and are very variable. The patient may develop delusions of suspicion and persecution; he thinks that the others in the ward are talking about him and that his food is being poisoned. In heart cases I have known several patients to refuse all medicine on that account. In other cases they are noisy and hilarious with ideas of grandeur and importance. Rarely they are suicidal but several cases are recorded where the patient has thrown himself out of the window or otherwise taken his life. I have for many years been in the habit when lecturing to nurses of impressing upon them the difficulty in nursing the patients in some heart cases. They are especially irritable, suspicious, and ungrateful for all that is done for them and they often take intense dislike to nurses and medical practitioners without any apparent cause. Acute mania sometimes develops in the course of heart disease and I can remember two such patients being sent to the Portsmouth asylum who rapidly recovered on the improvement of the heart. It is not my intention to speak here of palpitation, tachycardia, or other neuroses of the heart, as they do not fall within the scope of this paper.

Kidney disease.—The relation of the brain and nervous system to the kidneys is very close and at present is little understood, but that the kidneys may be stimulated or suppressed in their functions by purely nervous influences cannot be doubted. The surgeon cuts down upon a kidney or ureter for stone but none is found; the result in some cases is a temporary or permanent suppression of urine. In other cases of suppression of urine from bladder or urethral disease the fact of cutting down on the kidneys and incising them will restore their function. What happens we do not know. I agree with Dr. G. Savage that there is no special form of insanity associated with kidney disease but in the later stages of chronic Bright's disease the brain seems to participate, although, perhaps, less than we would expect, until it is violently overcome by the uræmic poison. The patients are often found crying and on inquiry they exhibit marked delusions of fear and suspicion; often they are delirious, restless, irritable, and show mental failure until coma terminates the scene preceded by convulsions. As a great clinician observed, "The idle comments foretell the ending of mortality."

It is, however, to the manifestations of uræmia that I wish especially to draw attention. Without any previous warning a patient may be seized with a violent epileptic attack, the fits being of great severity and rapidly passing into the status epilepticus. During pregnancy or when labour is commencing a woman may suddenly become maniacal and may pass into a condition of eclampsia. The mental symptoms here totally overshadow the bodily ones and it is recognised that the patient is in great danger. In both these dangerous conditions total unconsciousness is rapidly reached and general convulsions are the rule. In the gouty contracted kidney, especially in young adults, acute mania is not uncommon and I can remember the cases of three patients who were sent to asylums as lunatics when suffering from this condition. Commencing with restlessness, headache, and insomnia the patient very rapidly passes into a violent state of mania with delusions of fear and suspicion and often ending in death. In another form of uræmia the first symptom noticed is a hemiplegia or partial paralysis with no brain lesion discoverable post mortem to account for it, and I have seen patients with twitchings, cramps, and hiccough who were quite unable to sleep for several days, the mind remaining quite clear to the end. In some patients the mental distress is pitiable to witness, especially in the dyspnœic form with Cheyne-Stokes respiration or in the condition known as "renal asthma." When a medical man is called to a patient who is irritable, restless, and resistive, with twitchings or even convulsions, or where paralysis or coma is present, he must always have in his mind the possibility of uræmia. It is often impossible to distinguish these cases from cerebral hæmorrhage or poisoning and I have on quite a score of occasions seen cases post mortem whose fracture of the base of the skull or apoplexy turns out to be uræmia and nothing more. I have also had patients sent to hospital and asylum as lunatics who were in the early stages of uræmic poisoning.

Gout.—The exact etiology of gout is unknown but among other theories the nervous one has many adherents. The this lack of natural reserve is often very remarkable and appears to be due to a defect of that higher form of cognitive relation which, as I have said, comes very near to, if it be not as high as, moral consciousness.

The following case may serve to illustrate these points. A girl, aged seven years, whom I saw by the kindness of my friend Dr. F. E Batten, had had epileptiform attacks at intervals of a few weeks since the age of 12 months, associated with right infantile hemiplegia of the same duration. Intellectually the child was evidently defective, though only to a slight degree; she had not learnt to talk until fully three years old, but with only 12 months' teaching she had learnt to read short words and could count readily; she could also write the letters of the alphabet fairly distinctly. She described pictures intelligently and accurately. She was said to be very jealous and if much attention was paid to other children in her presence she would sometimes attack them, pinching them or striking them. Passionateness had been more marked formerly than now; at the age of five years she was said to have been "dreadfully violent"; for instance, one day when her mother was in the garden and she was not allowed to come out she flew into a rage, seized a stick, and deliberately smashed the window, and any such thwarting of her wishes was liable to produce an outburst of passion in which she would fling things recklessly about, including cups and saucers. Not the least striking of the qualities shown by this child was her lack of reserve. On entering my consulting-room she walked straight up to me, a complete stranger, and said, "I want a book"; on receiving a picture-book she exclaimed effusively, "You dear doctor; you dear little doctor," and then proceeded to examine the bookshelves for herself and conversed at intervals in an airy way on various subjects, amongst other things describing a medical man whom she had seen previously as "a saucy doctor." She was also described as very self-willed and although she was obedient to a certain extent it appeared to be almost entirely the obedience of fear, for she was frequently punished for disobedience and had to be reminded repeatedly of the instrument of punishment to obtain obedience.

The heading "wanton mischievousness and destructiveness" calls perhaps for some explanation. At first sight it might be thought that such qualities were hardly related to defective moral control, but I think that a little consideration will show that not only have they a very definite relation to the moral deficiency which we are considering but that in these qualities *par excellence* we can discern the lack of those altruistic tendencies with which moral consciousness is chiefly concerned; and this lack, although it is natural, as I have shown, in the infant, and in a less degree in the young child beyond the age of infancy, may be unnatural when it persists in an older child. Let me illustrate my meaning by a comparison of two children. A healthy boy, aged 18 months, who had passed the age at which he cared to tear up books, paper, or anything he could tear, had recently shown a love of throwing things into the fire, no doubt for the pleasure of watching the weird and dancing flames, and perhaps with an almost unconscious pleasure in the power of arousing the flames at will; his action was, in fact, a method of self-gratification which in its total disregard for the possible injury to others by destruction of property obviously implied lack of moral control, a lack which was perfectly normal at that age. But the persistence of this infantile quality in an older child was accompanied by other evidence of a morbid moral deficiency. A girl, aged seven years, had always been backward but by no means extremely so; it was difficult to judge of her intellectual capacity from school attainments, for her attendance had been very irregular and she was so spiteful that it was necessary to separate her from other children in the class, for she would thump, bite, or pinch them, sometimes so severely as to break the skin. She had learnt to sit up alone at 11 months and to stand alone at 16 months, she had talked at 18 months, so that in these respects she was very little behind an average child. She had fits occasionally from infancy up to the age of seven years; she was well developed; her facies showed nothing suggestive of mental impairment; her head measured 19¾ inches in maximum circumference—that is, nearly one inch below the average for the age. The mother stated that since the age of about five years her mischievousness had given continual trouble. She would tear up books, and other things, and on one occasion had apparently deliberately set the drapery on the mantelpiece on fire and then sat and laughed and clapped her hands. Seen again at the age of 10½ years this girl, although apparently only backward, was as passionate and as spiteful as ever; in fact, the mother said that it was quite unsafe to leave her with other children. She was also cruel to animals—she would take up the cat and dash it down upon the floor with intent to injure it, and if it happened to cross her path she would kick it. Here, I take it, the child's act in setting fire to the drapery was, as in the former case, an act of self-gratification, but the lack of moral control and, no doubt, of moral consciousness shown in this and in her spitefulness and cruelty was altogether unnatural for the age, and that it was part of a morbid state was, I think, evident in the general intellectual deficiency and in the repeated convulsions. I mention this particular variety of mischief—the setting fire to property—because it is sometimes a prominent feature in the manifestations of a morbid defect of moral control in children who show no apparent impairment of intellect and in such cases it has obviously an important medico-legal aspect.

There is one other heading which, perhaps, wants some definition—namely, viciousness. By this I mean a lack of moral control in such things as concern chiefly the good of self—for instance, self-abuse or other pernicious habits. Dr. G. E. Shuttleworth tells me of a girl, aged 12 years, brought up in good position and apparently of normal intellect, who in addition to precocious sexual immorality would, if unable to obtain alcohol otherwise, drink the methylated spirit used for her mother's toilette.

There is no need for me to dwell upon the moral defect in children with general impairment of intellect; my only reason for referring to such cases is because I think they throw some light upon the conditions which underlie a morbid defect of moral control where there is no apparent intellectual impairment. It seems possibl in these children to discriminate between certain differences in the causation of the moral defect. We ca recognise, I take it, with certainty two groups, an probably three groups, of cases all showing defective mora control and yet differing considerably in the psychical condition which is associated therewith. In one group, as have already pointed out, there is absence, partial or complete, of the simple cognitive relation to environment an therefore moral control is impossible; in another th child is, or appears to be, in full cognitive relation wit environment so far as what one may call the simpler o lower form of cognition is concerned, but lacks that highe form of reasoning comparison which I have called mora consciousness. Again, I will illustrate my point by actua cases. A well-grown and pretty child, aged two years an four months, has had fits since the age of eight months an is an idiot of very low grade; he does not distinguis between people and it seems doubtful whether he distinguishes between animate and inanimate objects; he bite anything within reach and as he sat in the out-patient roo he worried the edge of the table with his teeth like a dog Two days previously he had seized his mother's finge between his teeth and had bitten it severely enough to mak it bleed. He has eaten his own fæces, soap, and such thing indiscriminately He is said to be passionate if thwarte in his endeavours. In such a case it seems evident tha there is a lack of the simple cognitive relation, the lowes form of reasoning comparison by which he shoul have distinguished his mother's finger from other objects, and therefore *a fortiori* he lacked that higher form o reasoning comparison by which he should have distinguished the character of his act as contrary to what I have called th moral idea.

Contrast with this another case. A boy, aged nine years, had been brought to me for mental deficiency. He had learnt to walk and to talk at two years but was very backward intellectually. After being at school for three years he could only read words of one syllable. The chief trouble with him however, was his passionateness, spitefulness, and disobedience. Any crossing of his wishes produced an outburst of passion, and he had repeatedly thrown knives at the othe children with little or no provocation and had also throw scissors at his mother. Recently he had stolen a shilling from his mother and after spending part of it brought back the change and gave it to her. The mother, a very intelligent woman, volunteered the statement that he seemed to have "no idea of right and wrong"; he seemed incapable of any sorrow for his misdoings. Subsequently this boy became so dangerous to the other children that it was explosive neuroses and the influence of depressing circumstances, physical or mental, point strongly to the part played by the nervous system in the disease. The extremes of mental action are met with in gout, from maniacal excitement to the most profound melancholia. In acute attacks the patient may be so irritable and bad-tempered as to be unapproachable; in cases of suppressed or retrocedent gout delirium, apoplexy, or coma may suddenly develop and terminate the disease.

Exophthalmic goitre.—In the interesting and complex disease exophthalmic goitre the nervous and mental symptoms are often the most prominent. In many cases the first symptom observed is a sudden change in the mental condition. The patient becomes abnormally irritable, excitable, and fidgety; her moral nature, too, is altered and she is untruthful, spiteful, and suspicious. Delusions of impending danger and suspicion are developed and she has all the appearances of a melancholiac. I have seen three such cases sent to asylum who improved immensely under the influence of nerve sedatives and were discharged quite recovered. I have also seen several cases of exophthalmic goitre where the mental symptoms have been absent and the patient has remained placid and good-tempered throughout.

Myxœdema.—In myxœdema a condition of mental weakness is produced by some alteration in the higher intellectual centres, producing a slowness of perception and conduction. It is, however, to be borne in mind that cases of myxœdema may develop acute attacks of insanity, either mania or melancholia with delusions of suspicion and hallucinations of hearing.

Diabetes.—Although there is no known relation between diabetes and insanity we sometimes see definite mental changes coexisting. As a rule a patient is irritable, fretful, and impatient in the earlier stages. In the later stages he becomes suspicious and distrustful of those around him and may even develop delusions. The condition of diabetic coma is too familiar for description and is often most difficult to diagnose until the urine reveals the disease.

Chorea.—We now come to another condition of which we know but little—viz., chorea. We are familiar with its manifestations but not with its cause. I am one of those who think that fright and sudden mental shock play a most important part in its production. I had a patient under my care two years ago who had three distinct attacks of chorea, all caused by a black dog at home. When this dog was got rid of the patient settled down and has had no further attack. The whole train of mental symptoms in chorea is one of nervous instability and fear. The patient is always in dread of something terrible going to happen and it is only when the medical man and the nurses thoroughly get his confidence that he begins to improve. In the more serious forms of chorea, such as chorea gravidarum, convulsions and coma rapidly ensue and death is common, whilst in a few rare cases insanity follows, and only this week I have sent a boy to the asylum who developed acute mania after an attack of chorea.

Acute infective fevers.—Amongst the numerous acute infective fevers I will only briefly refer to three—viz., typhoid fever, pneumonia, and rheumatism. In typhoid fever we have two distinct phases of mental disorder, one occurring during the acute febrile stage and the other appearing during convalescence. The nervous symptoms in some cases of typhoid fever completely overshadow all others and the patient may rapidly pass into a condition of raving mania most difficult to treat or to control; hence the old name for the disease, "nervous fever." The cause of this is toxæmia due to a most severe general infection in which the nervous system participates. In other cases the patient may pass into a condition of wakefulness with hallucinations of vision and hearing and even delusions, which may terminate in a sleep unto death. The acute stage may pass off and the patient during the third week may pass into a state of profound mental prostration, or a condition of imbecility or stupidity may ensue lasting for several weeks. The other important mental change is one of post-typhoid insanity, caused no doubt by nervous exhaustion and insufficient food, and it must be borne in mind that mania may follow ordinary starvation. In some types of typhoid fever insanity not uncommonly follows, but in my experience of a fair number of cases it always passes off and the patient makes a good recovery. I have made a careful observation of the mental changes during an attack of acute pneumonia. In the early stages the symptoms of wild delirium and even mania with all the symptoms of delirium tremens are due no doubt to the virulence of the poison and especially is this the case for some reason or other in apical pneumonia, especially the right apex. I have seen the worst mental symptoms in cases where only a small part of the apex of the lung was attacked and they are very fatal. The sleeplessness so often distressing to witness is due to cerebral irritation at first and then to cerebral exhaustion. It is to be borne in mind that a patient suffering from pneumonia is liable to sudden frenzy and may attack the nurse or patients or may even throw himself out of a window without any warning. I have never observed insanity to follow pneumonia. Mental symptoms in rheumatic fever are extremely rare, not including those, of course, due to hyperpyrexia. I have seen one patient develop acute mania with insanity which terminated in complete recovery after having delusions of grandeur and importance for six weeks.

I will only briefly mention without description the other diseases in which mental symptoms are common. We are all acquainted with alcohol—I mean clinically. It may in excessive doses produce all the symptoms of true insanity, as in addition to the familiar symptoms of delirium tremens delusions of all varieties may be present together with hallucinations of hearing and vision constituting for the time real insanity. Many hundreds of such cases have been sent to asylums and nearly all recover for a time. Arsenic, as we have seen recently, is capable of producing in association with alcohol a curious train of mental symptoms, chiefly depression and melancholia with delusions of fear and suspicion. They pass away slowly but surely and I have only seen two cases out of over 200 in which permanent insanity has remained.

Time will not permit me to speak of the mental symptoms associated with uterine and sexual disorders or to the temporary insanity which sometimes follows injuries and surgical operations, but I would just like to mention the case of a young woman who was sent to the Mill-road Infirmary as a lunatic of three years' standing, who was suffering from delusional insanity and who said that she was the Virgin Mary and was going to give birth to another Christ and so on. She had a large fibroid of the uterus occupying the whole abdomen and extending under the ribs. This was removed and with it the whole of her insanity passed away and she is now perfectly well physically and mentally.

There appears to be a very close relation indeed between the ovaries in the female and the testicles in the male to the nervous system. A few years ago it was a common practice to remove the testicles for diseases of the prostate, especially in elderly men. The operation was followed in several cases by most disastrous results; acute mania and delusional insanity followed by profound melancholia occurred in three cases under my own observation. The same dire effects follow sometimes in operations on the healthy ovaries and I think that a surgeon should hesitate before removing these organs *when in a healthy state* for any disease whatever.

I have seen three or four cases of raving acute mania with delusions follow the application of atropine to the eye, always in elderly people, with fortunately a good prognosis.

Now what is the object of this somewhat disjointed paper? There can be no doubt that physicians are now more alive to the fact that the mental symptoms arising in the course of a disease are often part and parcel of it and require just as careful treatment as the disease itself. Too often a patient exhibiting mental symptoms is certified and sent to a lunatic asylum when a little time and patience would have cleared the whole thing up. But, it may be said, where is the alternative? General hospitals and private houses are not equipped for the treatment of mental disease and with regard to the hospitals it is no doubt a grave defect.

There is a great want in Liverpool in the fact that there is no reception house or hospital for those suffering from mental disease and temporary insanity, both from the point of view of the patients and their relatives and the education of students. For instance, a man suffering from acute delirium tremens (and these cases are not uncommon in Liverpool) cannot be admitted anywhere in the city but to the workhouse hospital. These patients are the most dangerous lunatics for the time and yet they cannot be certified as legally insane. In the large Poor-law infirmaries and workhouses if a patient develops temporary insanity he is transferred to the mental wards and there he remains in many instances until he is cured, but in a general hospital or private house he is removed to a lunatic asylum, private or pauper, and is equally well cured there; but the question is, was it necessary for him to bear the stigma of having been signed as a lunatic when he was simply suffering from temporary mental aberration the result of bodily disease? There can be no question whatever that an asylum of some sort is the best place for the patient, but he need not be certified as insane, at any rate, until it is seen whether his insanity is likely to be permanent or not. These are the cases which swell up the recovery rate of admissions to asylums, especially those suffering from alcoholic insanity, and I have always very much doubted the recovery rates from organic insanity. I would like to see established in Liverpool, preferably by the corporation, a reception house for mental diseases of all forms where patients might be admitted in the acute stage of the disease and kept under observation for one month, and at the end of that time, if the symptoms had not passed off, either be removed by their friends or then certified for detention in an asylum.

After a long observation of lunatics—and I have personally certified over 2000 patients to asylums—I am firmly convinced that a large number of people are certified as lunatics throughout the country who are simply suffering from temporary insanity the result of, or associated with, some form of bodily disorder or toxic poisoning. These people are not really insane and should not be associated with lunatics. They quickly recover under proper treatment and I maintain that from every point of view it would be to the public advantage for them to be treated in a hospital for mental diseases, with expert physicians in attendance and a clinique of students to study the acute phases of mental disorder, and where the patient and his relatives might be spared the stigma of his having been detained in a public lunatic asylum as a certified lunatic.

Liverpool

THE TREATMENT OF EARLY MENTAL CASES IN A GENERAL HOSPITAL.[1]

By J. W. SPRINGTHORPE, M.A., M.D. MELB., M.R.C.P. LOND.,

PHYSICIAN TO THE MELBOURNE HOSPITAL; LECTURER ON THERAPEUTICS TO THE UNIVERSITY OF MELBOURNE; OFFICIAL VISITOR TO THE METROPOLITAN ASYLUMS, VICTORIA.

THE classical mistreatment of the lunatic was synchronous with the dominance of the metaphysical conception of the depravity of his volition, and died with its death, perpetuating its cruel existence, however, in the legal definition and procedure that still dare to misjudge man's responsibility by what the lawyers are pleased to call his knowledge. But the modern treatment of the insane, inspired as it is by the modern scientific spirit, is something very different and is ever advancing along lines of progressive reform, so that the phase of development of a community may almost be said to be mirrored by the manner and degree in which it deals with its mentally afflicted.

On looking round we find the following therapeutic details characteristic of the procedure of the most humane and scientific peoples—viz., some provision for early and doubtful cases in the shape of observation wards or receiving houses; the scientific classification of the insane; the separation of the curable in small wards or detached hospitals, furnished with all modern requirements and provided with fully-trained nurses in the proportion of at least one to five; the opening of outdoor departments; the fusion of hospitals and asylums, and the establishment at the latter of a consultant medical, surgical, and neuro-pathological staff; the transference of patients from one asylum to another; the licensing of wards in workhouses and the like for the harmless chronics; the boarding-out of increasing numbers by twos and threes in private families, and the official supervision of all private and individual cases. How far we in Victoria fall short of these signs of progress is known only too well to all who take an interest in lunacy matters, and the practical result with us has been that members of the profession here are often at a loss to know how best to deal with numerous individual cases. Too often, also, pauper lunatics enter the asylum through the doorway of the gaol, whilst some of our criminal insane have never got further than the inside of the gaol hospital. It is little wonder therefore that, wherever practicable, the better class are either treated *sub rosâ* in private establishments or sent out of the colony to better quarters abroad.

It was in view of these unfortunate circumstances and their tacit recognition by the authorities that for some years past I have from time to time attempted to treat some of my insane patients in the wards of Melbourne Hospital. The Government provision was so unsatisfactory and inadequate, there was no receiving house, the very names of Kew and Yarra Bend carried an indelible stigma, whilst by hospital treatment there might be for the students invaluable clinical material that they might otherwise never obtain, and for the patient earlier, and in many respects better, treatment. Most of the advantages of such hospital treatment require simply to be stated to be recognised and admitted:—1. There is no necessity to wait until some unfortunate accident, *lâche*, or crime necessitates the tardily-written certificate. Treatment is thus available much earlier than usual—a point the importance of which to the patient, to his friends, and to the community can scarcely be over-estimated. 2. It places "borderland" and early cases under the same therapeutic conditions that have been found efficacious against the kindred hysteria, cerebrasthenia, and bodily disease generally, and it gives the patient greater opportunity of having the frequent co-existing or causative bodily disease properly and promptly attended to. 3. It does away with the false distinction between mental and bodily disease and it altogether avoids the stigma and disgrace attaching to "lunatic" and "asylum." 4. There is no signing of certificates with its, at times, serious sequelæ to both patients and medical men, and the natural convalescing ground, the home, is much earlier and more readily available.

These are advantages, both fundamental and immense. But the plan has also its limitations and disadvantages. We had, and have, no cells for separate cases; the nursing staff was, and is, not organised for lunacy work or specially trained in lunacy charge; whilst the hospital grounds are too small even for ordinary recreation and the public strain upon our beds, their much greater individual cost, and the restrictions of the law are such as to render it impossible to deal with more than an occasional patient or to keep him under treatment for more than a limited number of weeks. Most, if not all, of these disadvantages, however, seem to me matters of arrangement rather than of principle.

My actual experience may be summarised as follows: 1. Under existing conditions it was found impossible to attempt to deal with maniacal cases. Outside the general wards there was no place for them except the refractory ward and that was fully occupied by the "D.T.'s," the cases of noisy delirium with fever, and the like, and structurally the building itself was quite unsuitable. 2. We were, however, able to observe and to treat cases of early progressive dementia and of early general paralysis (especially those in which the mental symptoms were late in their development) until we were satisfied that the asylum was the proper place for them. 3. The hospital wards have also been excellent observation wards for many doubtful cases in which it was impossible to say definitely whether the mental condition was or was not the outcome of some undercurrent bodily disease but which, under any hypothesis, required skilled treatment forthwith. Under this heading I have thus dealt with cases of disseminated sclerosis; with mental crises; with cases of syphilitic frontal lepto-meningitis and brain tumours; and with the mental phases of utero-ovarian disease, of hypochondriasis, and of doubtful general paralysis It is beyond question that the critical atmosphere of a hospital medical school and the skilled reports and care of highly-trained sisters are of the greatest value in promoting the diagnosis and treatment of these mental conditions. Other cases, also, complicated with epilepsy, in which the epileptic status was frequent, or unusually severe, or in which the amnesia and dementia were becoming marked, or the onset of actual insanity was suspected, could be kept under observation until it was decided what was best to be done and meantime they could be treated to the best of our ability. 4. Cases of actual lunacy, also, in which the condition was undoubted but the necessity or advisability of signing certificates was more or less problematical, have been satisfactorily treated in the wards. Thus I have treated cases of transient mental unsoundness due to inanition, to neglect, or concomitant with phosphuria, until the patients have been discharged cured. I have also treated cases of sudden dementia, stupor attonitus, and other diseases, due to shock, fright, and the like, until they, too, have regained their mental equilibrium. And, most interesting of all, I have taken into the wards a number of cases of actual melancholia and in three at least I had the satisfaction of seeing them rapidly restored to health without any recourse to asylum certificates or treatment.

---

[1] A paper read at the April meeting of the Medical Society of Victoria.

One of these cases was that of a female, aged 24 years, of good family, but reduced circumstances, who, from the cheerless nature of her outlook, and some religious self-condemnation, had become morbid, left her home before daybreak, and was found by a policeman half-dressed and wandering near the Yarra. She was speechless, declined her food, and had to be watched and looked after. Her medical attendant suggested asylum treatment, but after careful examination I undertook to try the effect of general hospital treatment. She was admitted into Ward 13 on April 24th, 1901, nursed, dieted, and otherwise treated according to the indications. She soon began to take notice, became interested, slept, ate, and conducted herself along normal lines, until in three weeks she was sufficiently recovered to be restored to her family, both they and she being very grateful for the restoration, and especially for the fortunate avoidance of asylum reminiscences.

The second case was that of a girl, aged 18 years, who had become cataleptic after typhoid fever and who made a good recovery in Ward 13; 12 months later (May 11th, 1899) I was called to see her in a state of melancholic stupor after an acute onset. Here, again, there was no question of the need of prompt skilled atttention and justification even for asylum restraint but I decided to try the hospital before signing a certificate. A good deal of difficulty was experienced in dealing with her in a general ward but by the tact of the sister and the hearty coöperation of the nurses the patient was able to go home some seven weeks afterwards and came to see us a month later thoroughly well both mentally and bodily.

The third case was also one of a young girl, aged 18 years, always somewhat dull, and never rising above the third class at school. Partly from overwork in a factory and partly from excessive religious emotion she had become completely changed, melancholic, delusional, and was recommended by her medical attendant for asylum treatment. I took her, however, into the hospital on June 2nd, 1900. For a few days we had to send her down into the refractory ward, but six weeks later she was able to go away with her mother and was seen several months later as well as ever she was. In all three cases the hospital environment, the nursing, and the going out with different nurses, contributed very largely, in my opinion, to the early and satisfactory result.

This brief summary will suffice to show that the wards of a general hospital can fulfil a very useful function in the treatment of early mental diseases. And it is equally evident that, with some reorganisation and rearrangement, this new and specially valuable utility might be considerably augmented.

No doubt most of the present disastrous hiatus between the onset of mental unsoundness and its asylum treatment would be satisfactorily filled by the establishment of a receiving house, provided that receiving house was large enough to accommodate all suitable cases, was properly equipped, was provided with sufficient ground, and was officered and nursed along the lines of a general hospital. And its usefulness, in my opinion, would be quadrupled if an outdoor department could be added to it and its name and scope widened into that of a hospital for early mental cases. But until such a receiving house is actually receiving patients, and even afterwards, it would also, in my opinion, be a natural and proper part of the usefulness of a general hospital, which is also a medical school, to make suitable provision for the reception and treatment of a certain number of such cases, and it will be an endeavour on my part to bring the matter prominently under the notice of our hospital staff and committee.

Since writing the above I have found strong corroboration of the position therein taken up in the report of a special meeting of the Edinburgh Medico-Chirurgical Society called to discuss the Treatment and Teaching of Incipient and Transient Mental Disorders in the Royal Infirmary of Edinburgh.[2] The meeting was a large and representative one and most of the managers of the Royal Infirmary of Edinburgh were present. Sir John Sibbald introduced the question in a paper which claimed that the early stages of mental disease required just that kind of treatment that a general hospital could best offer, and that the establishment of wards in the Edinburgh Infirmary would best remedy the present defective arrangements. He then enumerated the advantages to be obtained from such a new departure and suggested a time-limit of six weeks, at the end of which asylum treatment might follow in case recovery or death had not taken place. He dwelt also upon the advantage to the medical student in thus becoming duly equipped for one of his most serious future responsibilities. He was supported by powerful speeches by Sir John Batty Tuke, Dr. T. S. Clouston, Dr. J. O. Affleck, Dr. Urquhart, and others, the chairman of the General Board of Lunacy, and the advisor in lunacy to the Glasgow Parish Council, all of whom recognised the extreme importance of the proposal and its educational, preventive, and curative value. Finally, it was unanimously agreed "that this meeting urges strongly on the managers of the Royal Infirmary the propriety of seriously considering the expediency of providing wards within or in the immediate vicinity of the institution for the treatment of incipient, transient, and recent cases of insanity."

Melbourne.

TEMPORARY REMINISCENCE OF A LONG-FORGOTTEN LANGUAGE DURING THE DELIRIUM OF BRONCHO-PNEUMONIA.[1]

BY HENRY FREEBORN, M.B. EDIN.,

WITH REMARKS BY C. A. MERCIER, M.B., M.R.C.P. LOND., F.R.C.S. ENG.

THE patient was a woman, aged 70 years. She felt poorly on the evening of March 6th, 1902, and kept her bed on the 7th. I saw her on the 8th and found her complaining of headache and pain in the shoulders, back, and limbs. Her temperature was 102° F and her pulse was 100, regular, and strong. Examination of the lungs revealed slight bronchial catarrh (the patient was very liable to slight attacks of bronchitis and had to keep her bed for a few days at a time once or twice during every winter). Her condition on the 9th and 10th was about the same; there were less headache and pain generally, the temperature remaining between 101° and 102°. On the 11th the patient had passed a bad night, the respirations were quickened, the cough was troublesome, the pulse was 120, and the temperature was 105°. Examination of the lungs revealed increased bronchitis all over and on the right side of the back at the angle of the scapula increased vocal resonance and fine crepitations. There was no difference in the percussion note on the two sides. The lungs were not again examined thoroughly after this date until about the 20th because the condition of the patient would not allow it. When they were then examined the bronchial catarrh had disappeared all over. On the right side no trace of any patch of consolidation could be found, but on the left side at the back I found dulness over rather a large area with other signs of consolidation. This had quite cleared up three days after. The general condition of the patient remained about the same for two days, the temperature being between 105° and 106°, the pulse at this time being about 120 and strong. On the 13th the temperature fell rapidly to 98°, went up again for a short time in the afternoon to 101°, and fell again in the evening to 97°. On this day she coughed up a little rusty sputum, the only time she did so. At 9 P.M. I arrived to find her apparently dying. The pulse was quite uncountable, weak, and flickering. The nurse said that she began to change an hour before and was getting rapidly worse. Three minims of liquor strychniæ were given subcutaneously. In 10 minutes the pulse could be counted and in 20 it was fairly strong at 110. It was found necessary to repeat this dose every fourth hour and to give brandy and carbonate of ammonia freely until the 16th, on which day she began to improve and her pulse remained strong and slow without the help of the strychnine. On the 16th and 17th the bowels acted very freely six times in 24 hours; this was one reason for discontinuing the strychnine. Two doses of $\frac{1}{100}$th grain of digitalin were given on the 14th in conjunction with the strychnine, but the mixed injection did not act as well as the strychnine alone. The heart did not respond so readily to it, the effect passed off sooner, and the patient seemed more restless after each of these two doses.

[2] Vide THE LANCET, March 1st, 1902, p. 593.

[1] This paper appears in the Photographic Record of Clinical Teaching and Medical Science, June, 1902.

The chief point of interest in this case lies in the delirium. From the night of March 7th until the evening of the 13th (when the temperature fell suddenly) she was sometimes wandering while awake and continually talking in her sleep, but when spoken to would be perfectly sensible and so long as she was engaged with one of the attendants or doctor would answer questions, &c. When the temperature fell on the 13th she became quite delirious and remained so until the 16th, when she gradually returned to reason. On the night of the 13th and on the 14th she was found to be speaking in a language unknown to those about her. It sounded as if she was repeating some poetry sometimes or carrying on a conversation at others. She repeated the same poem time after time. This language was found to be Hindustani. On the 14th, in the evening, the Hindustani began to be mixed with English and she spoke to, and of, friends and relations of her girlhood. On the 15th the Hindustani had disappeared altogether and she was talking to, and of, friends of a later date in English, French, and German. The patient was born in India, which country she left at the age of three years and landed in England, after five months' voyage, before she was four years old. Up to the time she landed she had been under the care of Indian servants and spoke no English at all, her only language being Hindustani. On her coming to England the ayah was sent back and she then began to learn English and from that time had never spoken Hindustani. She apparently, on the 13th, went back in her delirium to her very earliest days, when she spoke again the first language she ever heard. The poem was found to be something which the ayahs are in the habit of repeating to their children and the conversations were apparently with the native servants, one being recognised as a request that she might be taken to the bazaar to buy sweets.

Through the whole delirium there could be recognised a sequence. As time went on the friends she spoke of were of later date and she took events in their proper order. She apparently began at the beginning of her life and went through it until on March 16th she had reached the time when she was married and had her children growing up boy and girl. It is curious that after a lapse of 66 years, during which time she had not spoken Hindustani, this language of her early childhood should be recalled in delirium. The patient now speaks English, French, and German (one as fluently as the other), but although she knows a few Hindustani words she is quite unable to speak the language or to put one sentence together. She says that she has no recollection (nor had she any before her illness) of ever having been able to speak Hindustani. The evidence that this language really was Hindustani is that she does not know, nor has she ever known, any other language except those mentioned in this paper. A lady who has lived much of her life in India and who speaks the language recognised the poem as one commonly in use amongst the ayahs and also translated some of the conversations which the patient carried on with her imaginary visitors.

Remarks by DR. MERCIER.—This case is a most striking, one may say a most dramatic, instance of a state of things which, in less impressive degree, is by no means uncommon and which, though abnormal, is not irregular. Events of the kind have been recorded before, but no case so complete, so extraordinarily perfect, and so well authenticated, has yet been published as far as I know. The classical instance with which all such occurrences are compared and classed is that of the illiterate maidservant recorded by Coleridge in his "Table Talk" who, while suffering from the delirium of fever, recited for hours in Greek and Hebrew. Many years before she had been in the service of a learned pastor who had been in the habit of reading these classics aloud in her hearing. She was totally ignorant of the languages in question and could not voluntarily reproduce a word of them. Yet in her delirium they boiled up to the surface, and boiled over.

It is to be noted that it was not the forgotten language alone whose memory was so strangely revived in this old lady's delirium. Her whole personality was transported back to her early years, and she lived over again the life of her childhood. She spoke of, *and to*, friends and relatives of her girlhood; she asked that she might be taken to the bazaar to buy sweets. Now this is the rule in certain cases of senile insanity. Perhaps I may be allowed to quote from my book on "Psychology, Normal and Morbid," to illustrate what is meant: "Along with this defect in the formation of structural memories"—and although Dr. Freeborn does not mention the fact I have no doubt that this process was completely defective in the case that he has described, so that when the old lady recovered she remembered nothing of what occurred during this period of her illness[1]—"there frequently goes an excess of those memories that remain from long past experience. Not only are these memories preserved, but they are recalled with exaggerated frequency and vividness. The memories of boyhood, for instance, are not only retained, but they are reproduced with excessive frequency and with a vividness which in middle life was unattainable. We often witness in the dementia of old age that not only are the experiences of the day forgotten, not only are the experiences of youth remembered, but the memories of youthful experiences thrust themselves forward with such vividness and persistence that they become the dominant feature in consciousness, and the old man literally lives his youth over again. To such a degree does this vivid reappearance of memories attain that it sometimes invades the province of perception, and the veteran addresses his grandchildren by the names of schoolfellows of his own who have long been dead, and with whom he has had no dealings since his boyhood. It seems as if structural memories were laid down in the nervous system in strata, the memory of each successive experience overlying the memories of previous experiences; and as if, in senile loss of memory, the removal of the upper layers allowed of an over-activity of those that remain, on the principle, so familiar to neurologists under the name of 'loss of control.'"

That this old lady was not insane in the ordinary use of the term, but was suffering from the delirium of bodily illness, goes to corroborate my favourite doctrine that not only are delirium and insanity the same thing, but that any weakening illness, especially if suddenly weakening, may be, and I should go further and say must be, attended by weakening of mind. If the patient had remained in the same mental condition after her recovery from the bodily illness no one would question that that condition might be rightly characterised by the term insanity. Yet the improvement of the mental condition *pari passu* with the recovery of the bodily illness indicates the dependence of the one upon the other.

The sequence of events in the course of her recovery was most remarkable. She gradually passed through the stages of her life, beginning in infancy and taking them, as Dr. Freeborn says, in their proper order, until, upon her complete recovery, she brought events down to their present date. Nothing so dramatically complete has ever come under my own observation, though I have seen cases in which the period of life lived through again has varied. It is a very common occurrence for persons who have acquired, so completely as to think in it alone, a language which is not that of their childhood, to lose that language in illness or in other stress and to return to the language earliest acquired, even when this had been almost or quite forgotten. I have had under my care during the last year an old lady whose native language is English, but who had subsequently acquired, in the order given, a perfect colloquial mastery of French and Italian and a competent knowledge of German. She is now 76 years of age and finds that she has lost her German, and in a severe attack of bronchitis she lost both French and Italian and was left with English alone. Her health is feeble and her mastery of Italian fluctuates with it. The great interest of the present case is that the language should have been discontinued so very early in life, that the patient had not only forgotten it but had forgotten that she could ever speak it. But, as Coleridge's case shows, the previous ability to speak a language is not necessary for its reproduction, and it is unlikely that the child herself had sung the verses. She probably reproduced them from hearing, as the servant girl reproduced the Greek and Hebrew. The gradual advance in the period of the patient's reminiscences, as her health improved, goes to corroborate, for what it is worth, my hypothesis of the stratification of memories. I do not put it forward as a very illuminating hypothesis, but in this very obscure region even a glimmer of light is grateful.

---

ROYAL DENTAL HOSPITAL OF LONDON.—This institution has received the sum of £500 from the trustees of Smith's (Kensington Estate) Charity.

THE INFLUENCE OF AGE UPON THE INCIDENCE OF OPTIC NEURITIS IN CASES OF INTRACRANIAL TUMOUR.

By H. DOUGLAS SINGER, M.D., M.R.C.P. Lond.,
SENIOR HOUSE PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

This paper owes its origin to the fact that three cases have recently come under the writer's observation in which symptoms referable to a gross lesion of the brain have led to an erroneous conclusion as to the nature of the disease. In two of these cases the necropsy revealed the presence of a new growth which had been unsuspected during life, whilst in the third case, that of a patient aged 25 years, thrombosis of the middle cerebral artery, due to syphilitic endarteritis, gave rise to symptoms which had been attributed to the presence of a cerebral tumour In none of the three cases was optic neuritis present at any time.

Of the three cardinal signs of intracranial new growth optic neuritis is certainly the most important, and it is customary to attach considerable weight to its presence or absence in any particular case. It is the object, therefore, in this article to investigate a number of cases of intracranial tumour which have progressed to a fatal termination but which have never presented any signs of optic neuritis For this purpose the notes of all cases of cerebral tumour on which a necropsy has been performed at the National Hospital for the Paralysed and Epileptic since 1893 have been examined, and I take this opportunity of expressing my thanks to the members of the honorary medical staff for their kind permission to make use of their cases.

Optic neuritis is generally recognised to occur early and with great intensity in tumours of the cerebellum, while for some unknown reason growths in the pons Varolii, although situated in such close proximity to the cerebellum, are not infrequently unaccompanied by optic neuritis. For this reason the cases have been analysed in classes according to the situation of the tumour in the cerebrum, cerebellum, or pons.

1. *Tumours of the cerebrum.*—Among 74 cases there were nine, or 12·2 per cent., in which optic neuritis was absent. The nature of the tumour in all nine cases was that of a malignant infiltrating growth, either sarcoma or glioma. Two were multiple affecting both hemispheres and of the remainder six were on the right side and one was on the left. All involved the centrum ovale, either frontal, parietal, temporo-sphenoidal, or occipital, and one extended into the crus cerebri. Seven of the patients were males and two were females. The most striking feature, however, was the advanced age of the patients. The youngest was 42 years and four were over 60 years, while the average in the nine cases was 54 years. In four cases atheroma of the vessels was noted in the records, in two the vessels of the brain were said to be natural, but no examination of the general vascular system was made, in the remaining three there was no note of the condition of the vessels although the capsules of the kidneys were stated to have been adherent. The symptoms during life had existed for from six weeks to two years, in seven cases beginning with hemiplegia and in the other two with fits. Headache was more or less marked in four cases, absent in three, and not mentioned in two. Vomiting was noted as absent in five cases, present in one, and was not alluded to in three.

Turning now to the remaining 65 cases, they can be divided into groups thus:—1. Two cases in which during life the presence of optic neuritis seemed to be doubtful, the patients being aged respectively 60 and 64 years (in the latter swelling of the discs was found at the necropsy). 2. Seven cases in which optic neuritis developed while the patient was under observation. Two of these patients aged 50 and 35 years, had hemiplegia for one and two months respectively before the appearance of the neuritis. The remaining five cases appear to belong to a not uncommon clinical group in which for a long time before the onset of definite signs of intracranial growth there are epileptic fits, either general or localised in character The time during which the fits had existed before the appearance of optic neuritis in these five cases varied from two and a half to three and a half years. The ages were 23, 34, 45, 46, and 55 years. 3. Two cases in which the neuritis was of a chronic type, the patients being aged 32 and 41 years. 4. Four cases in which the neuritis was slight, the patients being aged 35, 44, 42, and 62 years. 5. Fifty cases in which optic neuritis was well marked The ages of the patients varied from 12 to 56 years, with an average of 28 years.

2. *Tumours of the cerebellum.*—In 13 cases, with the ages of the patients varying from four to 47 years, 12 showed intense optic neuritis associated with more or less well marked consecutive atrophy The single exception was a man, aged 34 years, with symptoms of 15 months' duration. In this case Mr. R. Marcus Gunn reported that the discs were high coloured but not swollen. The colour, he considered, might be due to the existence of hypermetropic astigmatism. In this case the tumour was small, four centimetres in diametre; it was tuberculous in nature, there was old cavitation of the apices of both lungs and recent tubercles were scattered through these organs. The inter auricular septum was imperfect and there were well marked venous congestion of the abdominal viscera and clubbing of the fingers Consequently we are justified in concluding that in spite of the early age the vessels were probably not normal.

3 *Tumours of the pons Varolii.*—In these cases optic neuritis may apparently be absent at any age. The records include 14 cases, in six of which this sign was not present. The occurrence of papillitis seems to depend largely upon the association of the new growth with hydrocephalus, in four of the cases without neuritis there was no distension of the ventricles, in the other two distension was present but was slight in degree, whereas among the eight cases with marked neuritis there was only one patient, aged four years, in whom the ventricles were not dilated. The ages of the patients in these 14 cases ranged from 18 months to 54 years.

4. *Tumours involving the cerebellum and the pons.*—There were two cases of this nature, in one of which, a patient aged seven years, there was marked optic neuritis, whereas in the other patient, aged 54 years, there was slight swelling of the right optic papilla but none of the left, although symptoms had been present for 12 months.

Conclusions.—Although statistics are sometimes misleading yet a table showing the occurrence or not of papillitis at different ages, given in percentages for the convenience of comparison, shows such striking features that it is worth recording The table does not include cases of tumour in the pons except where there was definite involvement of the cerebellum because there would seem to be some far more important factor involved in the non-occurrence of optic neuritis when this region is the site of the disease which is at present unknown.

Table showing the Percentages of the Occurrence of Optic Neuritis at Various Ages in 88 Cases of Cerebral and Cerebellar Tumour

Age	No. of cases.	Optic neuritis.				
		Well marked.	Late or slight.	Chronic.	Doubtful.	Absent.
Under 30 years	35	97·1	2·9	—	—	—
From 30 to 40 years..	18	76·6	2·2	1·1	—	1·1
" 40 " 50 .. —	21	61·9	4·3	4·8	—	19·0
" 50 " 60	7	28·5	57·1	—	—	14·3
Over 60 years ..	7	—	14·3	—	23·5	57·1

The average age of the nine cases in which optic neuritis was absent was 54 years, that of the 51 cases in which it was well marked was 28 years

These figures are supported by the cases which were published by Dr. S. J. Sharkey and Dr. Byrom Bramwell in connexion with the discussion upon the Localisation of Cerebral Tumours at a meeting of the Neurological Society in 1898.[1] The former mentions two and the latter three cases in which optic neuritis was absent, the patients' ages being 46, 50, 60, 54, and 60 years respectively, giving an average of 54 years.

---

[1] Brain, 1898 and 1899.

The above analysis appears to justify the conclusion that *absence of optic neuritis in intracranial tumour, exclusive of those occurring in the pons, is rare in cases under 40 years of age and becomes increasingly more frequent after that period of life.*

This result may be found to have an important bearing upon the mode of origin of optic neuritis in that it would appear *primâ facie* to be in some way dependent for its existence upon the healthy condition of the vessel walls.

Queen-square, W.C.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF STERNAL FISSURE AND FORAMEN.

By WILLIAM BENTON, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

DR. WILLIAM BRAMWELL, writing in THE LANCET of April 26th, p. 1177, describes a case of minute peritoneal hernia through a cleft in the xiphoid cartilage. The following case being similar will be of interest.

A young woman recently consulted me for pain behind the breast-bone which she thought was due to indigestion and for years she had been treated for it. The pain was worse when she stooped and she sometimes felt as if something became nipped in between two bones or at other times as if two bones rubbed over each other. I thought of a dislocated rib cartilage and told her I would like to examine her at home. On palpation I discovered a fissure leading down to a foramen in the lower part of the sternum and pressure over this caused the pain which she described as of two bones overriding. She had no symptoms of indigestion and the pain was in no way related to food. Mr. S. J. Wareham (my partner) saw her later with me and we agreed that the pain was probably caused by a protrusion of either pericardium or pleura occasionally getting nipped in the fissure. Her mother told me that the patient had suffered from rickets when she was a child.

Upton Park.

A NEW METHOD OF LOCAL ANÆSTHESIA FOR SURFACE OPERATIONS.

By E. A. CLOETE SMITH, L.R.C.P. LOND., M.R.C.S. ENG.

THE following method of producing local anæsthesia will sometimes be found useful for small operations. A solution is prepared sufficient in relative quantity for the surface to be anæsthetised and having the following proportionate composition: adrenalin chloride, two drachms; cocaine, five grains; and water, half an ounce. Lint four times doubled and folded so as to be of the size required is soaked in this and applied under a similarly shaped positive electrode. A large negative electrode is applied elsewhere and a current of from 15 to 30 milliampères is slowly induced and run for the space of from five to 10 minutes. The surface may then be washed with ether and any superficial operation performed painlessly and without loss of blood.

Westbourne-street, W.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The annual dinner took place at Pagani's Restaurant on June 3rd. The President, Dr. Douglas Kerr (Bath), occupied the chair and Sir Lauder Brunton, F.R.S., was a guest of the society.—A conversazione was held at 20, Hanover-square on the same evening, at which there was a very large attendance of Fellows and guests. Sir Lauder Brunton gave an address on "Some Health Resorts in the Mediterranean" which was illustrated by magic-lantern slides. Dr. Ivor Murray proposed and Dr. E. Symes-Thompson (the president-elect) seconded a vote of thanks to the lecturer.

MIDDLESEX HOSPITAL.

A CASE OF ENTERIC FEVER IN WHICH WIDAL'S REACTION REPEATEDLY FAILED, THOUGH A PURE CULTURE OF THE BACILLUS TYPHOSUS WAS OBTAINED FROM THE BLOOD.

(Under the care of Dr. W. ESSEX WYNTER.)

THE value of Widal's reaction in the diagnosis of enteric fever is somewhat diminished by the facts that on the one hand the reaction is certainly sometimes obtainable when no typhoid fever is present and that on the other hand the reaction may not appear although, as in the following case, it has been conclusively proved that the patient is suffering from the disease. At present we are unable to explain these anomalies, but we may reasonably hope that before long pathological chemistry will make the matter clear.

A well-developed, healthy-looking girl, aged 19 years, was admitted into Middlesex Hospital on Feb. 24th, 1902. This was her first illness and though feeling ill and unable to do her work for a fortnight she had not taken to her bed. The preliminary symptoms had been giddiness, loss of appetite, thirst, and dryness of the mouth. There had also been pain in the joints and abdomen with diarrhœa and there had been deafness for a few days. When first examined she was flushed, the eyes were very bright, and respiration was obviously hurried (36). The pulse was 104 and the temperature was 104·2° F. The tongue was characteristically furred and red, the abdomen was not distended, and the spleen was not palpable. Great tenderness was complained of in the upper abdomen and the lower part of the chest in front, the point of maximum intensity being one inch above the xiphoid. The apex of the heart could be felt in the fifth space half an inch internal to the nipple and superficial dulness extended to the third costal cartilage and to the left border of the sternum. The heart sounds were distinct and a systolic murmur could be heard all over the cardiac area.

The bowels acted five times on the day of admission, the motions being liquid and each lighter in colour than the previous one, diarrhœa continuing in a less degree for 12 days. On Feb. 28th a few rose spots were noticed on the abdomen and lower thorax and the diazo reaction was obtained in the urine. On March 3rd the spleen was first felt below the costal margin, though a definite increase in the area of dulness had been previously observed. On this date also it was noted that the pulse was small, rapid, and unsustained; there was evident congestion of the bases of both lungs with some bronchitis and the nose was swollen and dull red. Digitalis administered in brandy gradually removed these evidences of circulatory failure and by the 5th the general condition had materially improved, the temperature having subsided to normal during the night. On the 6th the temperature reached 103·4° during the evening and the following day an ischio-rectal abscess was discovered and evacuated. This had given rise to no pain or inconvenience; it contained an ounce or more of ill-smelling pus which yielded a pure culture of the bacillus coli, but no other organisms could be discovered either by microscopic examination or cultural methods. The temperature fell at once to 98° but rose on the following day and maintained a range of between 100° and 102° for the succeeding three weeks, this evidently being a relapse though of a mild type. The subsequent convalescence was uninterrupted and the patient left the hospital on May 10th. In this case the symptoms and course were definitely typhoidal, the temperature being unusually high and persistent, requiring the continuous use of the ice cradle for eight days in addition to several baths, spongings, and doses of antipyrin with antifebrin. There was a definite relapse and convalescence was tardy.

Widal's reaction was tried with a 1 in 40 dilution on the day after admission (Feb. 25th) and again on the 28th, but there was no agglutination even after 45 minutes. On the 28th the bacillus typhosus was isolated in pure culture from the blood obtained from the median basilic vein. The blood was collected by means of a sterile syringe, and about from 0·5 to one cubic centimetre was inoculated into flasks containing 500 cubic centimetres of broth. At the end of 24 hours two out of the six flasks showed turbidity of the broth. Plate cultures were then made from these broths and six colonies were picked off, all of which when tested as pure cultures gave the typical cultural reaction and were clumped by typhoid antitoxin serum at a dilution of 1 in 500. On the same day a dose of antityphoid serum was administered subcutaneously and this was repeated two days later (the agglutinative power was represented by 1 in 20,000). On March 5th *the blood still failed to agglutinate the typhoid* bacillus in a dilution of 1 in 40 On the 16th there was some indication of reaction but the report was returned as negative, and on the 29th "the blood gave Widal's reaction in a feeble manner." In spite of this apparent lack of antitoxin in the blood examined the temperature averaged 102° instead of 104° after the injection of anti-typhoid serum, complete defervescence occurring four days later on the twenty-first day of the disease according to the patient's history.

The bacteriology of this case was kindly undertaken by Mr. Leslie Milburn and the daily notes were taken by Mr. C. E. Lakin, house physician.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

TWO RARE CASES OF INTUSSUSCEPTION.

(Under the care of Mr. J. RUTHERFORD MORISON.)

BOTH the following cases are of great interest. According to Sir F. Treves's statistics[1] 8 per cent. of cases of intussusception are due to polypi and diverticula, and so these may be looked upon as distinctly rare causes. Early laparotomy is undoubtedly at the present day the only satisfactory treatment of intussusception.

CASE 1. *Intussusception due to an inverted Meckel's diverticulum; reduction and excision of the diverticulum* (reported by Dr. R. H. Dix, late house surgeon).—A boy, aged five years, was seized whilst at school on July 5th, 1901, at about 11.30 A.M., with severe pain in the abdomen and shortly afterwards he vomited. He arrived home about noon and his bowels were then moved. The pain came on in paroxysms about every five minutes and caused him to cry out. At 3 P.M. he passed some blood from the rectum. During the night the pains occurred about every 15 minutes and he slept between them. He vomited occasionally. The intermittent pains and vomiting continued till his admission into the Royal Infirmary, Newcastle-on-Tyne, at 9 P.M. on the 6th. Nothing had escaped from the bowels since the blood appeared on the previous day. On admission the boy looked seriously ill. His face was pale and anxious and his eyes were dark-rimmed and sunken, his skin was warm, the pulse was good, and his tongue was clean. The abdomen was not rigid or distended. In the left iliac region a distinct elongated swelling could be felt. Per rectum the tumour could not be reached with one finger, but on bimanual examination with a hand on the abdomen and a finger in the rectum, the tumour could be pushed down by the hand above and distinctly felt not in the lumen but through the wall of the rectum. The examining finger was not blood-stained on its removal.

An operation was performed by Mr. Morison at 9.30 P.M. (34 hours after the illness commenced). The abdomen was opened in the left iliac region by an oblique incision over the tumour which was found at once. The intussuscepted bowel causing it was drawn forward out of the abdomen. Some clear fluid escaped from the peritoneal cavity. The intussusception was six inches long in its unreduced state and involved only the small intestine. The mass was wrapped in a large warm flat sponge and steadily and firmly squeezed till its size was evidently lessened. The bowel was then steadily reduced by gentle traction from above and *pressure from below*. *On its reduction* a firm tumour of about the size and shape of the little finger could be felt through the intestinal walls in the lumen of the bowel fixed to the wall opposite to its mesenteric attachment. At the site *of attachment a definite dimple* was observed and this suggested that the tumour was an inverted Meckel's diverticulum which had formed the apex of the intussusception. A longitudinal incision one inch long was made in the intestine and the diverticulum, for this it turned out to be, was excised. The intestinal opening was closed transversely by a continuous catgut suture through all the coats and outside of this was inserted a row of Lembert's interrupted sutures of catgut. The intestine was cleansed and returned into the abdomen, the opening into which was closed by four tiers of catgut sutures. The condition is illustrated by Fig. 1 and Fig. 1A. The specimen showed an intestinal diverticulum turned completely inside out, measuring one and a half inches in length, becoming wider from base to apex and ending in a somewhat bulbous extremity. There were patches of gangrene in its walls, affecting chiefly its mucous membrane. The patient recovered.

[1] Intestinal Obstruction, 1899, p. 178.

CASE 2. *Chronic intussusception due to a polypus of small intestine; reduction and resection of gut with tumour* (reported by Dr. J. W. Heslop, late house surgeon).—A miner, aged 62 years, was admitted into the Royal Infirmary, Newcastle-on-Tyne, on July 10th, 1901. He had been in good health till four months previously when he began to have pains in the lower part of the abdomen of a paroxysmal character and very severe. Occasionally he was free from them for a week. Accompanying the pains there were noisy rumblings of wind and he could not pass any or get his bowels moved except with medicine and then with difficulty. During the last month the pains were very violent and lasted for from 16 to 20 hours at a time. They occurred nearly every day and were accompanied by forcible vomiting and profuse sweating. The pain was only relieved when his bowels were moved and this could only be brought about by the administration of enemata. During the spasms his bowels swelled and became hard, the swelling being more marked in the right lower abdomen than in other parts. The patient had lost two stones in weight since his illness commenced and looked very weak. On admission he was thin and pale and anxious-looking with normal pulse and temperature. Except for the abdominal condition examination discovered nothing wrong. There was marked distension in the right iliac fossa where a distinct rounded soft mass, about one and a half inches, could be palpated. This swelling was freely moveable. In the epigastrium just above and to the right of the umbilicus a definite hard nodular tumour, less than and not so moveable as the first, was felt. Rectal examination revealed nothing.

An operation was performed on July 16th by Mr. Morison. The abdomen was opened by an oblique incision extending from the back of the ileo-costal space to the middle line, in front dividing the rectus and other muscles. A large, rounded, firm swelling was found in the ascending colon, evidently an intussusception. It extended from the right iliac fossa to the middle of the transverse colon. By expression and traction the intussuscepted gut was readily reduced, except the last two or three inches. This was towards the end of the ileum and contained a firm rounded tumour which was at this time suggested to be a carcinoma invading the ileo-cæcal valve. The portion of intestine including it along with the thickened mesentery and some enlarged glands were excised. The mesentery and intestine involved in the intussusception were so thickened and altered by old adhesions that until the excised portion and cut ends were carefully examined it was not recognised that the portion removed concerned the ileum only and that the distal incision left two inches of ileum attached to the cæcum. The divided intestine was thickened and friable and was too rigid to allow of a lateral anastomosis which Mr. Morison prefers when a choice can be made. An end-to-end union was effected by a continuous suture of catgut through all the coats and outside of this an interrupted layer of catgut sutures. The loose omentum was drawn down and wrapped round the anastomosis. The opening in the abdominal wall was entirely closed by four tiers of interrupted catgut sutures. The portion of gut resected measured three and a half inches in length and had a diameter of one and three-quarter inches. The intestinal wall was very thick. The mass in its interior was found to be a rounded polypus of the size of a large walnut which sprang from the antimesenteric border (see Fig. 2 and Fig. 2A). On the outside of the intestine opposite the attachment of the growth there was a distinct pucker on the peritoneal surface but it led into no channel as in Case 1. A microscopical report by Dr. R. A. Bolam states that "the tumour consists of young connective tissue with numerous vessels. In parts the appearances suggest myxomatous change but this may be accounted for by œdema. The surface of it is covered by normal mucous membrane." The patient recovered.

FIG. 2.

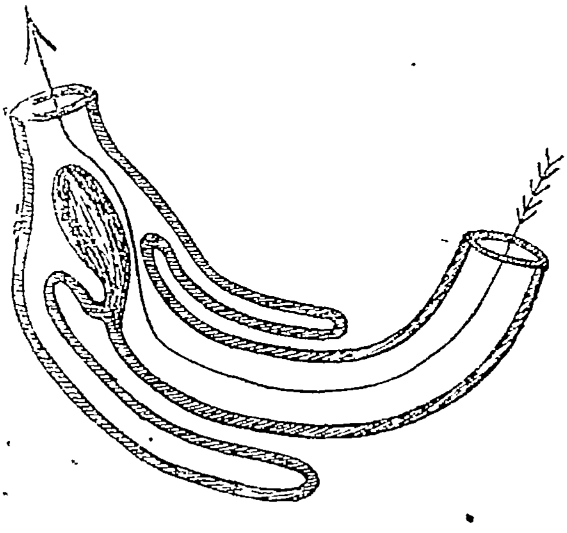

FIG. 2A

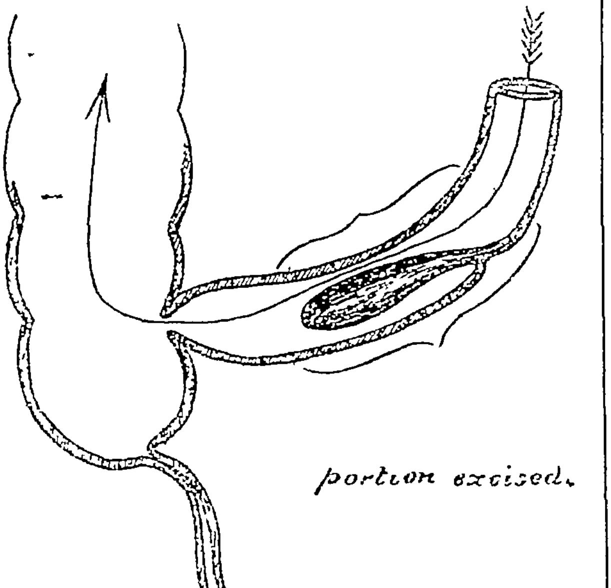

Diagram illustrating case of intussusception due to a polypus.

Dr P. Stewart of Langley Moor reports that the patient is in excellent health and works regularly in the mine. He has examined the scar by request for hernia and finds it perfect.

The diagrams, which were executed by Mr. G. Richardson, show the similarity of these two cases—an inverted Meckel's diverticulum in one and a polypus in the other forming the apex of the intussusception.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on the Etiology of Leprosy as Observed in the Soudan and in South Africa.—Delay in the Process of Growth and Development.

A MEETING of this society was held on June 10th, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. G. A. HANSEN (Bergen), in resuming the discussion adjourned from the last meeting of the society[1] upon the Etiology of Leprosy as Observed in the Soudan and South Africa, professed his belief in the contagiousness of leprosy. Fish-eating did not meet all the facts of the case. Formerly it was regarded as hereditary. His own view was that it was a specific disease. He mentioned instances which might have been regarded as hereditary which on further investigation proved to be due to contagion. The bacillus could be cultivated but only with considerable difficulty. If it could exist undestroyed in salted fish surely it would be easier to cultivate it in artificial media. All cases could probably be explained on the theory of contagion and his experience in

---

[1] THE LANCET, May 31st, 1902, p. 1535.

Norway went to support this. In Norway the people ate as much fish, salted and otherwise, as they formerly did, yet the disease was disappearing. Since 1856 lepers had been isolated, and at that time there were upwards of 2870 lepers in Norway. Since that time there had been a steady decline in the number of cases until at the present time there were only approximately 400 cases. In America none of the Norwegian immigrants, of whom there were an immense number, had developed leprosy and this proved that the disease was not hereditary. As regards the portal of introduction, he was inclined to believe it was introduced through the skin, probably through an abrasion. The local irritation was very small and the rate of development was very slow.

Dr. GEORGE THIN, referring to Mr. Hutchinson's paper, paid a high compliment to the painstaking inquiries of that author. Dr. Thin referred to the case of leprosy brought before the Medical Society of Dublin by Dr. J. Hawtrey Benson in which the patient's brother who had slept in the same bed subsequently developed the disease. Mr Hutchinson had referred to this case as an unique example of direct contagion, but it was by no means an isolated instance, and Dr. Thin mentioned other cases occurring in countries where leprosy was not endemic which were undoubtedly due to direct infection. Turning to the theory of the conveyance by food, this same idea had occurred to him when he was in China, but it was not tenable. Dr. Thin did not believe that leprosy was due either to an excess or to a scarcity of nitrogenous food. The bacillus had been cultivated outside the body by some Italian observers. It was necessary to take the bacillus from a patient at a time of fever when the microbe was specially active. As to the history of leprosy in South Africa and the first cases at Stellenbosch referred to by Mr. Hutchinson, he (Dr. Thin) did not think it unlikely that the disease might have been brought from the north or from the interior of Africa. The Royal Commission on Leprosy had investigated the question and had reported that leprosy was propagated independently of fish or any kind of food. It was greatly to be regretted that no legislation had been enacted for the segregation of lepers in India and now that Mr. Hutchinson had adopted the view of its contagiousness Dr. Thin hoped that adequate measures of prevention would be carried out. Wherever a leper went leprosy was sure to arise.

Dr. PATRICK MANSON thought they knew little or nothing really how leprosy was spread, though he entirely supported the view of its contagiousness. The disease was, he believed, analogous to tuberculosis. There was a very remarkable similarity between the two bacilli, but in neither case could it be proved exactly how the microbe was introduced. He would like to ask Mr. Tonkin whether the negroes of the Soudan in the Lake Chad district were in the habit of eating fish. He agreed with Dr. Thin that neither a deficiency of nitrogenous food as suggested by Mr. Tonkin nor the salt fish theory propounded by Mr. Hutchinson was tenable. Ainhum had no relation to leprosy. The preliminary lesions of leprosy were by no means always symmetrical and were not always associated with constitutional symptoms. He had been informed that the Dutch prisoners of war in Ceylon, in order to pass the time, had been trying to cultivate the leprosy bacillus and after trying several media they had at last succeeded in cultivating the bacillus on salt fish. He quite agreed with Dr. Thin's remarks about the necessity of legislation in India. As to the portal of entrance, Mr. Tonkin's suggestion about the clothes seemed extremely probable.

Sir WILLIAM KYNSEY had seen a great deal of leprosy in Ceylon. Dried fish was used universally in Ceylon. It was imported in very large quantities and it all went inland, but leprosy was confined to certain foci along the coast. He asked if the leprosy contagium might not be contained in human milk?

Sir T. LAUDER BRUNTON had been struck by the superficial resemblance of leprosy to syphilis, and when he had charge of the throat department of St Bartholomew's Hospital he was struck by the resemblance between syphilitic lesions and those of leprosy His opinion was that leprosy resembled other infectious diseases in this respect, that for the development of the disease the microbe and a suitable soil were both equally necessary Professor Unna of Hamburg had suggested the free administration of hydrochloric acid, as much as 15 grammes per diem in cases of leprosy. Possibly this acted by rendering the blood acid or less alkaline. The trimethylamine contained in the brine used for curing fish was a strongly alkaline substance, and when consumed it possibly rendered the blood more alkaline than normal and so acted detrimentally.

Dr. T. M. YOUNG had seen leprosy in Siberia, China, and other places. The motility of the bacillus when examined under the microscope suggested to his mind an analogy between the leprous and malarial organisms. He had not found that the leprosy bacillus was very common in the open sores of fishermen, and this did not support the view that the discharges of the ulcers were the source of contagion. His experience did not support the view that leprosy was in any way proportionate to the fish-eating habits of various peoples.

Dr. G. A. HERON regretted the abortive character of the Leprosy Commission. The conveyance of leprosy by salt fish was at present based purely on theory. Such questions must be settled in the laboratory. Why had not the bacillus been found in the salt fish? He (Dr. Heron) entirely agreed with the remarks of Dr. Thin and Dr. Manson. Certain facts brought out in the inquiries of the Commission still remained to be answered. For instance, in this report published in 1891-92 it was shown that out of 464 lepers in India 99 had never tasted fish. In another batch of 200 46 had never eaten fish. Altogether, there were in India 162 lepers who had never taken fish.

Dr. A. P. HILLIER, in criticising Mr. Hutchinson's paper, wished to ask a series of questions. For instance, was it only salt fish which conveyed the disease? and, if so, ought it not also to be conveyed by fresh fish? The fact that a leper stated that he had never seen other lepers was not one which recommended itself as an argument. Dr. Hillier mentioned the case of a Dutchman in South Africa who contracted the disease though he had never to his knowledge been anywhere near a leper. Later it was found that the Dutchman's Hottentot groom had been developing the disease without his own or his master's knowledge.

Mr. TONKIN, in reply, had never seen ainhum and leprosy occurring together. As to fish, it was very seldom consumed in Northern Nigeria and only in a very few tribes was it customary. It was very difficult to find fish in the markets of the natives. Fish was certainly a negligible element in the spread of the disease in the Soudan.

Mr. HUTCHINSON, in his reply, remarked that the transference by food and contagion pure and simple were the two opposing theories. He was living daily in expectation that the bacillus would be found in fish. This, of course, must be the crucial test of his theory. All the speakers had passed over the difficulties of the contagion theory. How was it that, in spite of the numerous attempts, the disease had never been inoculated? And yet some of those present had stated that scratches constituted the portal of entry of the disease. The facts against the contagion hypothesis were very strong. If a native's statement that he had not been in contact with a leper could not be believed, so also they could not trust his statement that he had not eaten fish. Mr. Hutchinson fully admitted the view of "stomach contagion," but whether the bacillus was actually in the fish or whether fish stimulated the bacillus to growth he could not say. He would not advise the shutting up of lepers. Instructing them in hygienic principles would be preferable.

A paper by Mr HASTINGS GILFORD, entitled "An Account of a Disease which is Characterised by Conspicuous Delay in the Processes of Growth and Development (Ateleiosis)," was read in abstract by the Secretary.

EPIDEMIOLOGICAL SOCIETY.

A Case of Supposed Hæmorrhagic Small-pox.—Syphilis among a Community of Khonds.

A MEETING of this society was held on May 30th, Mr. SHIRLEY F. MURPHY being in the chair.

Papers were read by Mr. SHIRLEY MURPHY and Dr. E. KLEIN on an obscure case supposed to have been one of Hæmorrhagic Small-pox in the person of a nurse from a home near the Strand which was reported after death to Mr Shirley Murphy by Sir Hugh R. Beevor, but which had in his absence been attended by Dr. F. Spicer. The patient had for three weeks preceding her illness been nursing the proprietor of a restaurant in an adjoining street who was suffering from acute rheumatism, but together with the other nurse in attendance she had slept and taken her meals at the home, there being no accommodation at the house of the patient. The house was also in such an insanitary condition that neither they nor the cooks could eat on the premises, which swarmed with rats. There being a suspicion that the case might be one of plague a post-mortem examination was made about 12 hours after death by Dr. W. H. Hamer and Dr. Young, assistant medical officers of health of the County of London, in the presence of Mr. Shirley Murphy, Dr. F. J. Allan, medical officer of health of the City of Westminster, and Dr. Klein who took specimens of the blood from the right ventricle and sections of the petechiæ for bacteriological and microscopical investigation. Dr. Spicer reported that she had been taken ill on Dec. 5th, 1901, and that she went to the home on the next day. He was not called in until the evening of the 7th when he found her to be suffering from all the symptoms of an acute malignant fever like typhus fever and complaining of severe general pain. There were bile staining of the conjunctivæ, a peculiar dusky flush of the face, with puffiness extending over the scalp and neck as far as the clavicles, and here and there a hæmorrhagic spot. On the front of the chest there was a faint rash like that of early scarlet fever or measles, but there were no petechiæ or papules though it was the fourth day of the disease. The ears, the nose, and the throat were normal. On the 8th she was evidently moribund and semi-comatose; the conjunctivæ were of a deep yellow with hæmorrhages, the duskiness, now deep brown, extending over the whole trunk which was covered with hæmorrhagic spots, those on the limbs resembling the rash of typhus fever. She died at 4 A.M. on the 9th, her temperature having five hours previously fallen from 104° to 98° F. Dr. Hamer described the post-mortem appearances as a purpuric eruption from pin-point petechiæ to blotches of the size of a split-pea, especially marked over a triangular area with its base at the level of the umbilicus and its apex at the pubes, chains of petechiæ extending to the axillæ and others grouped on the the arms and the thighs. There were conjunctival hæmorrhages and petechiæ on the pericardium, the sac containing several ounces of fluid. The appearances of the eruption and of the conjunctivæ were, in his opinion, characteristic of hæmorrhagic small-pox and resembled those of many cases observed by Mr. Shirley Murphy in the epidemic of 1871. There was, however, no evidence that the patient had been directly exposed to infection, though there were at the time many cases of small-pox in the neighbourhood of the Strand and Drury-lane, and two nurses, friends of the deceased, had been engaged at the hospital ships for the purpose of gaining acquaintance with that disease. One went to the ships on Sept. 2nd and passing to the shelter on Nov. 23rd returned to the home on the 27th; the other went on Sept. 23rd and having returned remained at the home from Nov. 23rd to the 27th and then went back to the ships. Whether the patient contracted the infection through either of these was not known, but the incubation period would have been not over seven days in the one case and not over 11 days in the other. On Nov. 13th she had gone to visit a friend suffering from enteric fever at Gravesend, but there had been no illness among the nurses during the year and none of them had recently attended any infectious case. As a precaution all persons with whom she had been associated were vaccinated on the evening after her death.—Dr. KLEIN then gave an account of his bacteriological examination of the blood illustrated by lantern slides. Film specimens and, better still, plate cultures showed (1) the diplococcus pneumoniæ in abundance and (2) a few individuals or colonies of a hitherto undescribed bipolar bacillus, morphologically closely resembling that of plague but wholly different in the culture appearances, which were not unlike those of Friedländer's bacillus. It was virulent to mice subcutaneously and to guinea-pigs intra-peritoneally only, but not at all to rats. From the slime with which it was surrounded he suggested the name of "bacillus myxoides." In the absence of any evidence of small-pox infection he considered the presence of the two pathogenic bacteria—indeed, that of the enormous numbers of the diplococcus pneumoniæ—sufficient to account for all the phenomena of the case. Again, sections of the skin showed hæmorrhages into the lymph channels and corium with pneumococci, but no trace of the changes in the epidermis or of the formation of loculi characteristic of variola, though the fourth day of the disease had been already reached. As a bacteriologist and microscopist only he was by no means inclined to the diagnosis of small-pox.—Sir HUGH BEEVOR insisted on the highly insanitary state of the house in favour of a septic causation, and pointed to the fact that the vaccinations of the nurses had been performed too late; yet, intensely infectious as hæmorrhagic small-pox was, no one had been attacked, though many of them had not been vaccinated for 15, 20, or more years.—Dr. SPICER was also doubtful and he called attention to the black vomit, the bloody stools, and the vaginal discharge.—Dr. HAMER, who believed that the case was one of hæmorrhagic small-pox, attached little importance to the non-appearance of the eruption and Dr. E. F. WILLOUGHBY agreed, though he doubted the correctness of the diagnosis, and referred to a case that came under his notice in 1870 or 1871, in which after eight days, during which it had been taken for one of acute meningitis, the appearance of a copious eruption, all but confluent, was followed by relief of all the symptoms.—Dr. E. W. GOODALL saw nothing in the phenomena inconsistent with the diagnosis, but he believed that many cases so regarded were simply mixed septic infection.—Dr. H. T. BULSTRODE thought that this case resembled those of hæmorrhagic plague described by Bogden, but Dr. H. Meredith Richards objected that the distribution of the eruption in the three cases of hæmorrhagic plague that he had seen was quite different from that in those of hæmorrhagic small-pox, though in the former death occurred before any adenitis appeared and in the latter before the few papules had time to become pustular. The only difficulty to him was that so infectious a disease as hæmorrhagic small-pox had not spread.—Staff Surgeon W. E. HOME, R.N., and Mr. J. S. C. ELKINGTON referred in like terms to cases of hæmorrhagic small-pox and plague respectively that they had met with in the East.—Dr. KLEIN could not agree with M. Maurice that hæmorrhagic small-pox was essentially the product of a mixed infection, though he admitted that a number of various bacteria were present in all cases of small-pox and that there were malignant fevers due entirely to mixed infections in which, as in this case, pneumococci predominated.

Captain LEONARD ROGERS, I.M.S., sent a contribution which was taken as read, on an Outbreak of Syphilis in a small isolated community of Khonds, among whom it appeared to have been introduced about 20 years ago from the town of Sonpur, some 30 miles distant, and to have spread unchecked by medical treatment of any kind and favoured by their low standard of morals, overcrowding, and want of cleanliness until the time that the famine operations brought this obscure tribe under the notice of the authorities. More than half the population of both sexes and all ages were found to be suffering from the disease and its consequences in every stage, from the primary infection to the remotest tertiary symptoms and in either the acquired or the congenital form. Besides those sequelæ known but now rarely seen in Europe, ulcers and fissures in the horny soles of their bare feet were very frequent, especially among the men; and though the lowering of their vitality by famine might have aggravated the symptoms and led to the frightful mortality, there had been no evidence of any tendency *in the disease to die out.*

DERMATOLOGICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on May 14th, Dr. J. J. PRINGLE being in the chair, when the following cases of interest were shown.

Mr. MALCOLM A. MORRIS brought forward a girl, aged nine and a half years, who was becoming progressively disfigured by the appearance of numerous Telangiectases all over the face. There was no deformity resembling true nævus on any part of the skin and in addition to the disfigurement it could only be noted that she had rather a feeble peripheral circulation and showed mottled pigmentation of the skin on the legs. The changes in the face were stated to have commenced at three years of age and had been spreading steadily since then. The question of treatment by electrolysis or other means was discussed, but it was felt that the difficulties in the case rendered the prospect of a good result very uncertain.

Mr. MORRIS also brought forward a young woman who was afflicted with an extraordinarily extensive Pigmented Mole on the Back and peculiar changes on the right arm. The pigmented mole on the back occupied practically the whole of the left side of the trunk. It was little raised, showed deep pigmentation, and a slight amount necessary to send him into an asylum. Unlike the previous case, this boy was, at any rate to a large extent, in cognitive relation with his surroundings, but he lacked moral consciousness, so that, as in the previous case, but for a different reason, moral control was deficient.

But in addition to the two groups of cases thus illustrated we must recognise a third, in which the child is not only in cognitive relation with his surroundings but also shows moral consciousness even with reference to the particular activities in which he manifests his lack of moral control. For instance, a boy, aged six years, is backward; he learnt to talk at two years and to walk at two and a half years; he knows his letters but cannot read words of one syllable after being at school for more than two years. He appears to be deficient intellectually but not to any considerable degree. He is very passionate; if the other children offend him in any way he will run at them and strike them or bite or kick them; he is mischievous, will turn on taps to let the water or gas escape; he is very disobedient and it is found very difficult to prevent his throwing things into the fire which he delights to play with. In order to set fire to pieces of paper he will secretly take away boxes of matches and hide them in his clothes, under his shirt, or elsewhere until he can get away from his mother to light them. After the outbursts of passion and attacks on his brothers and sisters he seems ashamed of his actions, is genuinely sorry for them, and sometimes says that he "didn't mean to do it." Here it seemed clear that there was some degree of moral consciousness—the child could, at any rate, with regard to some activities, differentiate between right and wrong.

This third group of cases is of considerable importance in its bearing on some of the cases with no general impairment of intellect which I shall consider subsequently. The defect is neither in the cognitive relation to environment nor apparently in moral consciousness, and yet the control of activity in conformity with moral consciousness is markedly defective. Have we here to do with a disorder of the will? Is it possible that inhibitory volition is imperfectly developed as the result of the same morbid condition of the brain which has impaired the intellect? There seems to be no *a priori* reason why volition should not be liable to impairment like other mental processes; and if inhibitory volition is of late development both in the individual and in the race it is easy to understand that it will be specially liable to defect in development and to disorder when developed. And there is some evidence that it is a late development; in the individual the control of the expressions of the emotions, such as joy, grief, and fear, is noticeably weak in early life, the infant and the young child weep at causes which would be quite inadequate to produce such an effect in an older child, who in turn will weep over causes which in a higher race would fail entirely to produce any such expression of emotion. Darwin in this connexion has quoted (from Lubbock) the case of a New Zealand chief who "cried like a child because the sailors spoilt his favourite cloak by powdering it with flour." That a similar defect of inhibitory volition with regard to the emotions may result from disease without apparent impairment of intellect is shown in the curious outbursts of weeping which are so common in children with chorea, who at other times show no such lack of control. A very similar failure of inhibitory volition in connexion with grief and fear is not uncommon with gross cerebral lesions—for example, intracranial tumour I shall have occasion to say something more on this point in a subsequent lecture—here I will only point out that some of the activities in which defect of moral control is shown are expressions of the emotions and are associated with those other manifestations of uncontrolled emotion, such as excessive grief and fear, which are not in any way concerned with moral consciousness; it is probable, therefore, that the defect of moral control in regard to these particular activities, at any rate, is in some cases due to a failure of inhibitory volition.

It would seem, then, that we can recognise in children with defective moral control in association with general impairment of intellect three grades, if I may so say, of deficiency, all characterised by lack of moral control—(1) defect of cognitive relation to environment; (2) defect of moral consciousness; and (3) defect of inhibitory volition. Moral control, in fact, might be compared to a three-storey building; the second floor is impossible unless the one below is present and the top storey—inhibitory volition in accordance with moral consciousness—is impossible unless the two lower floors are present.

Such a categorical statement of the building up of moral control and of the causation of its deficiency of course makes the matter appear much simpler than it really is; no one of these defects is likely to be complete, and hence it is often extremely difficult to make out how far any one of these defects is the chief factor in producing the moral failure in any particular case, and it is quite conceivable, nay, highly probable, that all three may sometimes share in its production.

This consideration of the psychical defects which are concerned in the causation of moral deficiency in children with general impairment of intellect leads up to the important question as to the relation of the moral defect in such cases to the general disorder of intellect. Is the moral defect necessarily proportionate to the intellectual defect? Can we say that this child is of more feeble intellect than that, and therefore will manifest the greater deficiency of moral control? The very question implies that I am drawing a distinction between the manifestations of intellectual capacity and those of moral control. As I have already pointed out, both the simple cognitive relation to environment and the moral consciousness which are essential to moral control imply a reasoning comparison, albeit of very different degrees of complexity, and may therefore be regarded as intellectual processes, and consequently in so far as defect of moral control is dependent upon the lack of either of these it is itself a manifestation of impaired intellect.

But granting all this it may still be that the intellectual process or rather complex of processes concerned in the comparison between right and wrong, between the moral idea and opposing stimuli, may be sufficiently specialised—functionally, of course, I mean, not locally—to allow of its being disordered or defective apart from any such general defect as is commonly recognised as idiocy, imbecility, or insanity. One might bring forward an analogy in the well-known differences in capacity for particular intellectual acquirements which are shown by different individuals. Each of these acquirements represents a particular combination of intellectual processes, and often it appears to be the particular combinations rather than the separate processes which are at fault. A very small capacity for such reasoning as is required in arithmetic or higher mathematics is common enough where the capacity for other intellectual acquirements is even above the average. May I illustrate my point by another analogy? A boy, aged 12 years (for the notes of whose case I am indebted to Dr. R. Farrar of Chiswick), was fully up to the average in the ordinary school accomplishments but was entirely unable to spell words correctly from dictation. For "and then what rogues they are; while one monkey is busy cracking a nut" he wrote, "and torse wothe roeg eose Woet one loreoy is beoys coreing a beors." Here the special combination of mental processes involved in spelling from dictation was defective, although none of the separate processes involved in that particular combination could be singled out as in any way deficient and in other combinations of these same processes there was no defect whatever. No doubt this condition is explicable on a physical basis in a failure of connexion between parts of the cortex, but the case illustrates the possibility that the particular combination of mental processes concerned in moral control may be defective whilst other combinations of the same processes in what we ordinarily recognise as intellectual acquirements may show no defect whatever.

But apart from any such theoretical probability the clinical phenomena show, I think, that there is ample justification for considering moral consciousness and moral control as liable to disorder apart from the more general intellectual functions. Perhaps the most striking feature of these cases of defective moral control with general impairment of intellect is the disproportion in many cases between the moral and the intellectual deficiency—if capacity for the ordinarily recognised intellectual acquirements may be taken as the gauge of intellect. It is true that in the lower grades of idiocy and imbecility where the simple cognitive relation to environment is lacking or defective the resulting defect of moral control appears to be directly proportionate to the general intellectual defect, and this is only natural, for the cognitive relation to environment is just as essential a factor in general intellectual development as in the development of moral consciousness, so that in so far as this cognitive relation is lacking, both intellectual and moral failure will result—the two, in fact, are dependent on one and the same cause and to this extent are related to one another. But in of hairiness. The more striking changes were seen in the tissues in the inner side of the right arm from the middle of the forearm to the axilla, which was occupied by an extensive diffuse pendulous tumour. This part of the nævus was important not only on account of its extent but on account of the fact that it was spreading progressively all round its margin, this extension being heralded by an advancing line of pigment on which small nodules appeared. The characters of this portion of the deformity of the skin resembled certain of the extensive tumours in neuro-fibroma. It was found that the growth of the tumour was exceedingly slow, and on the question of operation being raised it was determined that on account of its position and extent complete removal by surgical procedure was unadvisable in spite of the indications of extension observed.

Dr. Pringle presented an old man, aged 84 years, who showed Multiple Patches of Epitheliomatous Change in the Skin. They occurred on the face and other positions and one such area had been removed years ago from the right cheek and the scar had remained sound. The skin showed marked senile atrophy and numerous warty overgrowths of the type known as senile or seborrhœic were also present.—The members who discussed the case were agreed that the epithet "seborrhœic" as applied to these warts implied an unwarrantable assumption of their etiology.

Dr. Pringle also brought forward a young woman who was suffering from Acanthosis Nigricans (Congenital), and stated that it was of special interest in this case to observe that an almost uniformly warty growth on the lips had been present since birth. It could be seen that there were already slight pigmentation and rugose thickening of the skin of the neck and axilla, and it was reported that there was considerable wart-like hypertrophy of the skin in the neighbourhood of the anus and vulva. The hand showed the peculiar velvety appearance caused by minute papillary overgrowths and there was some enlargement of the papillæ of the tongue. The patient appeared perfectly healthy and there was no evidence of any form of abdominal disease.

Dr. T. Colcott Fox showed an elderly woman who had suffered from large Tumours on the Forehead and Scalp for three years. The right temple and the right side of the scalp were obscured by the presence of numerous coalescing bluish pink tumours, varying in size from that of a bean to that of a walnut. The aspect of the mass of overgrowth suggested serious malignant disease. Dr. Fox drew attention to a few smaller lesions on other parts of the body which were ordinary examples of molluscum contagiosum and showed that even the large tumours possessed the characteristic appearance and contained the usual material. He mentioned certain cases in which molluscum contagiosum had been known to assume the gigantic type and stated that he considered that the present was an instance of this form of the disease, a diagnosis in which all present agreed. Dr. Fox spoke of the treatment which he proposed to adopt.

Dr. Fox also showed a young woman with a characteristic Acneiform Tuberculide Eruption on the face and hands. Dr. Fox remarked upon the great improvement which had occurred in this case by treatment with biniodide of mercury

An interesting group of three cases of "Ringed Eruptions" and Hyperkeratosis Eccentrica was presented for comparing the appearance of these very rare and still unexplained maladies. The case of hyperkeratosis eccentrica was the example of the disease already shown and reported by Dr. J Galloway. It was the first case of this disease identified in this country. Most of the cases had been reported from Italy, but a few had been observed in the United States of America and Germany and in France. It was immediately conceded that the disease affecting the epithelial tissues mainly was quite different in its characters from the ringed eruptions also shown. A second case of the malady had now been observed by Dr. E O. Perry at Guy's Hospital.—Dr. H. Radcliffe Crocker showed one of the cases of ringed eruption, describing it as the malady which he recognised as "granuloma annulare." In this patient, a young man, the eruption produced characteristic circinate outlines on the backs of both hands, surrounding the metacarpophalangeal joint of the right index finger, and on the outer side of the left index finger. The margin showed the elevated smooth outline of diseased tissue inclosing an area of skin more pigmented than the surrounding skin and with slight signs of atrophy. With this was compared the case of a young lad previously shown and reported by Dr. Galloway under the name of "ringed eruption of the extremities," or "lichen annularis." In this case the hands were also affected, the eruption being curiously symmetrical and one or two were observed on the left pinna.—Dr. Galloway showed the histological structure of his case and the opinion of the society was that these two cases, being diseases specially involving the cutis vera, were clearly distinct from the case of hyperkeratosis eccentrica, and most of the members concluded that the two cases of ringed eruptions were examples of the same malady, and hoped that a further comparison of the cases of Dr. Crocker and Dr. Galloway might throw some light on the etiology of this rare condition

Dr. J. H. Sequeira brought forward a patient who had been previously shown by him to the society and who had presented at that time numerous soft pigmented growths, resembling the Multiple Pigmented Idiopathic Hæmorrhagic Sarcoma of the type described by Kaposi. Many of the growths, especially on the hands, had now diminished in size and almost disappeared, but on the legs numerous pigmented and hæmorrhagic nodules still persisted. The patient ascribed the marked improvement in his condition to the use of soda baths, with which he treated himself on his own initiative.

Dr W. Lee Dickinson and Dr. E. G. Graham Little gave an account of a case of Lymphadenoma in which flattened tumours had occurred, involving the true skin. The histological characters of the cutaneous growth were exactly similar to that of lymphatic gland.—A discussion ensued as to the exact nature of the growths in the skin

Dr. Whitfield showed for Dr G. F. Still a child on whose back were numerous finger-nail-sized Patches of Pigmentation. Dr. Whitfield remarked that it was difficult to obtain a definite history of the onset of the lesions which had produced the pigmentation. Factitious urticaria could not be elicited and the exact nature of the lesion had not yet been ascertained. It appeared probable that the case was a mild one of urticaria pigmentosa.

Dr. Graham Little presented a child suffering from Discoid Scaly Eruption, mainly on the lower extremities The case was brought forward in order to elicit the opinion whether the eruption belonged to the class described by Brocq as "érythrodermie pityriasique en plaques disseminées." Much interest was taken in the case on account of the present discussions on skin diseases producing improper cornification and desquamation of the epidermis The majority of the members present considered that there was no reason for differentiating the disease in this particular case from a true eczema.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

The History of Eczema in the Past Century in England.—Exhibition of Pictures Illustrating Skin Diseases and of Cases.

The annual meeting and conference of this society was held on May 22nd, Dr A. J Harrison being in the chair.

After the transaction of business Dr. Harrison quitted the chair which was taken by Dr. H. Stowers, the new President.—A vote of thanks to the retiring President was proposed by Dr R. L. Bowles, seconded by Dr. H. H Phillips-Conn, and carried with acclamation.—Dr. Harrison, in his reply, alluded to the often renewed proposal that the society should from time to time hold meetings in the provinces and gave reasons why such a step might be desirable. He could say that Bristol would welcome such a new departure and possibly there were other towns with a similar ambition He offered the subject for consideration of the members - The new President made some introductory remarks in which he described the work done by the society and expressed the hope that in future questions concerning treatment would have more time devoted to them.

Dr Unna of Hamburg read a paper entitled "The History of Eczema in the Past Century in England." He pointed out that 100 years ago eczema, as they now understood it, did not even exist. Seguin Henry Jackson in his "Dermatopathology," translated into German in 1794 did not mention eczema It was true that Aëtius had in past times employed the term but it was for a different affection. Willan (1793-1816) grouped together a number of cases of vesicular dermatidue to trauma of chemical or physiological nature—e.g., plasters, vesicants, mercury, &c., and cases due to sun exposure (heat eruption). For this class he chose the name "eczema." It was clear that the observation of the cases of mercurial dermatitis gave the chief impulse to this generalisation and influenced the description given, for Bateman recommended readers who wished to understand eczema to study works by Alley, Butter, and others on mercurial disease. So it was clear from the definition he gave that, for Willan, eczema was a traumatic, vesicular, non-infectious malady, and clearly Willan was not the founder of the eczema conception of to-day. Had his idea been followed we should possess to-day after 100 years, under the name "eczema," a most instructive and important chapter on traumatic dermatoses. The single inconsequence in the otherwise clear eczema chapter of Willan-Bateman was the admission—in addition to the two forms, eczema solare and eczema rubrum (hydrargyria)—of a third variety, eczema impetiginosum, to cover partly those cases that, starting, for instance, from a blistering plaster, spread over the body and partly those which in the form of grocers' and bricklayers' itch belonged to Willan's impetigo figurata and so to the eczema of to-day. This form was really included more on etiological than morphological grounds and, following Willan's definition, clearly did not belong to the class of eczema. The mention of these chronic occupation diseases that showed diffuse inflammation and notable itching and that were hard enough even now to separate from eczema proved in fact an Achilles' heel. Plumbe (1827) was a strict Willanist, stricter than Bateman, for he rejected Bateman's third variety, eczema impetiginosum. He was the last true follower of Willan, not only in England, but elsewhere. The English authors who followed came more and more under the influence of the rising Parisian school of dermatologists and notably of Rayer. Following the teaching of Biett, that Willan had erroneously only described acute eczema and had overlooked the chronic, Rayer added to the three varieties of Willan-Bateman, which, by the way, he largely remodeled, a fourth—namely, chronic eczema. This chronic eczema was an entirely new creation, pieced together by the master mind of Rayer from separate details that in Willan lay scattered principally in the chapters on Impetigo and Porrigo. His description was based on 11 cases of his own. He was the first to note and to describe the regional modifications, in which he had been since followed by most authors. This great service would have had far greater value had Rayer not mixed up his new disease with Willan's acute eczema and, in fact, taken the latter as its "acute beginning." This unhappy amalgamation was due to the fact that Rayer could not have studied Willan properly. Willan and Rayer were describing entirely different affections, and it was the failure of the last-named to appreciate this that led to most of the subsequent confusion. As a result of the French remodeling of English views on eczema it happened that a traumatic, rare, acute, not itching affection became converted into one that was non-traumatic, common, chronic, and itching. The naval surgeon Jonathan Green (1835) was the first victim of the confusion in England. He appeared to follow Willan in that he spoke of traumatic eczemas and even introduced a new one caused by sulphur, but he parted company entirely when he went on to say that such eczemas differed from the proper c constitutional forms in their easy curability. Dr. Unna next referred to the early work of Erasmus Wilson (1842) and he showed that it was just a selection from other authors and that, owing to its great popularity, this book served to perpetuate the existing confusion. Anthony Todd Thompson (1850) who edited Bateman's work was a decided Willanophile, but he showed the influence of the French school when he spoke of an outer and an inner (i.e., constitutional) eczema. T. Moore Neligan (1852) drew attention to the fact that eczema of the face and scalp in children appeared in the strong as well as in the weak, in the scrofulous and in those not so tainted, in the well nourished and in the reverse. And yet he fell back on a constitutional cause for this type. Meanwhile a great step forward occurred in France. Devergie pointed out that Rayer's eczema by no means always commenced with Willan's clear-clustered vesicles and that it often did not show any vesicles in the whole of its course. Hence he separated the two and gave to Rayer's form four fresh symptoms—namely, redness, violent itching, a secretion that stained and stiffened linen, and a *status punctatus*—i.e., fine holes in the skin from which serum poured. It might be thought that, with the separation of Willan's and Rayer's eczema and with the entire removal of artificial inflammations, even as the "acute beginning" from the latter, that the *status quo ante* had been again restored. Such was not the case. Hebra, who appeared in the "sixties," had on English dermatologists even more influence than Devergie. On the strength of very insufficient experiments with croton oil and other irritants he managed to reintroduce into the eczema chapter the traumatic dermatoses that Rayer and Devergie had so carefully rejected, and his great authority covered for many years all that was untrue and incongruous in the muddle called eczema. Erasmus Wilson was entirely under Hebra's influence and this in spite of the fact that he was the first to introduce a chapter on traumatic skin affections. He freed himself, however, entirely from Willan in that he held, with Devergie, the vesicle as an inconstant, non-essential feature. Tilbury Fox (1873) believed himself a Willanist and in consequence announced his intention to oppose the authorities of his time. But his work was full of incongruities. He was no true Willanist, only the greatest Willanophile among moderns. McCall Anderson (1874) was the first, after Hebra and Wilson had already and occasionally recognised the scaling patch as the initial symptom of eczema, to declare it to be the most important form of commencement. Dr. Unna here pointed out how unfortunate it was that Rayer called his disease "eczema" and how unfair it was to ascribe to Willan the confusion that would have been avoided had his ideas been followed, and he then passed on to consider briefly his own work. Hitherto Willan's eczema alone had possessed a clear etiology, while that of Rayer was the plaything of unproved hypotheses and unfruitful theories. In 1890, before the British Medical Association in session at Birmingham, he declared Rayer's eczema on clinical grounds to be a parasitic affection. After 12 years in which he had confirmed his theory he had the satisfaction of knowing that in England Morris, in America Elliot, in France Leredde, and in Germany Bockhart, had in great part accepted and enlarged his views. Hence the future study must lie in bacteriological domains and the new century could already record a start. Possibly the progress in chemistry and physiology might be of even greater importance. Clinical study alone could do no more. It must proceed hand-in-hand with microscopical, bacteriological, and chemical investigation if the future development of the eczema conception was to be possible.—Dr. P. H. PYE-SMITH proposed, and Dr. H. WALDO seconded, a vote of thanks to Dr. Unna which was carried unanimously.

A fine collection of pictures illustrating interesting Skin Diseases was displayed. Among the exhibitors were Dr. H. RADCLIFFE CROCKER, Dr. STOWERS, Dr. E. G. GRAHAM LITTLE, Dr. E. STAINER, Mr. N. BISHOP HARMAN, and Mr. A. SHILLITOE.

Cases were sent for exhibition by Dr. STOWERS, Dr. P. S. ABRAHAM, Mr. T. H. KELLOCK, Dr. LITTLE, Dr. T. D. SAVILL, Dr. A. EDDOWES, and Mr. SHILLITOE.

CLINICAL SOCIETY OF MANCHESTER.

Enteroptosis.—The Treatment of Early Malignant Disease of the Larynx.—The Etiology and Pathology of Gall-stones.—Exhibition of Cases.

A MEETING of this society was held on May 20th, Mr. HERBERT LUND, the President, being in the chair.

Dr. ARNOLD W. W. LEA read a paper on Enteroptosis based upon observations of 54 cases met with in a series of 600 women patients. Several cases illustrating this condition were shown to the society. In enteroptosis there was, he said, general downward displacement of the viscera. The transverse colon often lay just above the symphysis and the greater curvature of the stomach might be found anywhere between the umbilicus and the pubes. The small intestines sank into the lower part of the abdomen and pelvis owing to elongation of the mesentery. Nephroptosis was present in 70 per cent. of the cases. More rarely also the liver and spleen were displaced downwards. Uterine displacements were commonly associated with enteroptosis and many cases of prolapse and chronic retroflexion occurred as part of a general ptosis of the viscera. In other instances this condition was associated with adhesions produced by pelvic peritonitis. Retroflexion was present in 42 per cent. and pelvic peritonitis with adhesions in 25 per cent. of these cases. The ætiological factors producing enteroptosis were the following: 1. Impairment of the general health and feeble muscular development. This was often associated with anæmia and dyspepsia. It might occur in young women but its frequency increased with each decade of life. 2. Increased size of the abdominal cavity, as after pregnancy, especially if repeated at short intervals with insufficient rest after delivery. This might cause (*a*) general stretching of muscular and fascial structures with impairment of elasticity or (*b*) wide separation of the muscles forming a ventral hernia. The distension produced by tumours, collections of fluid, &c., acted similarly. 3. The wearing of *corsets*. The compression of the waist and the weight of the skirts tended to force the viscera downwards and favoured the development of enteroptosis. Patients suffering from this condition could not wear the ordinary corset with any comfort. 4. Influence of peritonitis. The abdominal wall was relaxed and the coils of bowel distended after an attack of peritonitis. The great omentum often became adherent to the pelvis in cases of pelvic peritonitis. These adhesions might cause constant dragging on the colon, the stomach, and the intestines, producing descent of the viscera by traction. The symptoms produced by enteroptosis were very variable and did not depend on the degree of the displacement. Many patients were neurasthenic and showed evidence of general malnutrition and feeble muscular development. The most constant symptom was dragging pain in the abdomen and loins which was much aggravated by exertion and completely relieved by lying down. This appeared to be produced by dragging on the coils of bowel and mesentery and consequent irritation of sympathetic ganglia. Gastro-intestinal symptoms the result of gastro-duodenal dilatation were common. Obstinate constipation was usual, though sometimes attacks of diarrhœa occurred. The displacements of the individual organs gave rise to special symptoms referable to them. Many cases treated as moveable kidney were examples of general ptosis of the abdominal organs. Pain in the left hypochondrium was present in a large number of cases. The diagnosis was rarely difficult. The abdomen was relaxed and it bulged laterally. Marked epigastric flattening was observed if the patient stood erect. The abdominal walls were often thin and the movements of coils of bowel and of the stomach could be plainly seen. The abdominal walls might show (1) general muscular relaxation; (2) loss of elasticity and over-stretching of the fascia especially in multiparæ and elderly women; and (3) wide separation of the recti muscles. The linea alba might be from three to four inches in width. The latter was readily recognised if the patient breathed deeply whilst reclining or if attempts were made to sit up; the edges of the recti muscles then projected clearly on each side of the stretched linea alba. The stomach was frequently dilated, as shown by splashing sounds, by palpation, or by distension with gas. The liver was usually normal in position, though it might descend two inches on assuming the erect position. The kidneys showed various degrees of mobility and usually could be readily felt, although nephroptosis alone was not sufficient evidence of descent of the viscera (the right kidney could be palpated in from 45 to 60 per cent. of women). The transverse colon might be recognised much distended lying below the umbilicus. There was no certain physical sign indicating descent of the small intestines, although post-mortem evidence showed it to be usually present. In many cases aortic pulsation was very marked. The pancreas might also be felt as a flattened band lying just above the umbilicus. The treatment of enteroptosis must be directed (1) to improvement of nutrition and the removal of any causal factors, such as tight-lacing, over-exertion, &c.; (2) to the regulation of the stomach and bowels by careful dieting and medicinal treatment; and (3) to the restoration of the muscular and fascial supports of the abdominal walls. For the last-named purpose gymnastic exercises were of very great value and if carefully carried out did much to restore muscular and fascial strength to the abdominal walls. The following exercises were specially recommended: (1) the patient lying down with folded arm raises herself into a sitting posture; (2) the patient lying down and maintaining extension of the knees raises the legs to a position at right angles to the abdomen, each limb being raised singly, then simultaneously; and (3) deep breathing, especially movements of inspiration with a closed glottis, and after the lungs have been emptied by forced expiration. Each of these exercises should be carried out from six to 12 times night and morning. They were most efficient in general muscular weakness and relaxation but also were of benefit in wide separation of the recti muscles. It was usually necessary to support the abdominal wall by a properly fitting belt or binder. This must reach below the hips and the object was to lift up the abdominal viscera from below. Unless this was accomplished no relief was afforded. The straight-fronted corset which was designed to overcome suprapubic projection was specially suitable for cases of enteroptosis since the waist was not unduly compressed and the greatest pressure was applied below the umbilicus and in an upward direction. The belt and corset might also be combined in one. They should be applied whilst the patient was lying down before the viscera had descended. In some cases it was necessary to apply special pads if the patient was thin or the kidney was very mobile. In some cases surgical treatment might be required. Nephrorraphy was of value if combined with treatment for the general ptosis of viscera. Hepatopexy for ptosis of the liver had been carried out with benefit. In cases of extreme gastroptosis with dilatation various operations had been practised, such as shortening of the gastro-hepatic omentum, gastrorraphy, or gastropexy. Gastro-enterostomy had been successfully performed for extensive dilatation with gastro-duodenal stenosis. Various operations might be practised on the abdominal walls, such as resection of folds of skin and fascia. The best method was to expose the edges of the separated recti muscles and to unite them in a common sheath. If there was evidence of traction from adhesions in the pelvis or elsewhere exploratory abdominal section should be carried out.

Dr. E. S. YONGE made some remarks on the treatment of Early Malignant Disease of the Larynx. He showed two patients upon whom he had operated for epithelioma, respectively nine months and eight months previously. In each instance thyrotomy, with excision of the diseased tissues, had been the procedure adopted and the results up to the time of exhibiting the patients had been excellent.

Dr. E. T. MILNER gave a brief account of the Etiology and Pathology of Gall-stones and reviewed the modern surgical treatment for the relief of this condition. He showed two patients who had undergone the operation of excision of the gall-bladder—one 13 months after cholecystotomy for empyema of the gall-bladder and gall-stones and the other a primary cholecystectomy in a woman, aged 59 years, for cholecystitis and gall-stones, with frequent biliary colic, &c. He expressed the opinion that the more radical operation of excision of the gall-bladder would ultimately prove to be justifiable in a larger proportion of cases than at present.

Dr. A. T. WILKINSON showed a case of a man with an Intrathoracic New Growth which involved the right lung and caused pressure on the superior vena cava, resulting in intense congestion of the head and neck. The apex of the lung was dull; immediately below there was natural resonance, but the lower lobe was dull. The superficial veins of the thorax and abdomen had become immensely enlarged and had to some extent relieved the blood stasis in the head and neck.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Ascending Paralysis

A MEETING of this section was held on May 16th, Sir CHRISTOPHER J. NIXON, the President, being in the chair.

Dr. W. J. THOMPSON exhibited a case of Ascending Paralysis. The patient had been a drayman for the last two years and came into hospital on account of weakness of his legs; he had no loss of sensation and the reaction to the faradic current was normal. Eleven days afterwards he was paralysed from his feet up to the superior border of the thorax. He could swallow fluids but not solids. He remained in this condition for weeks and then slowly recovered. At present he was able to attend to his duties and his patellar reflex had returned.

Dr. A. R. PARSONS read a paper on Ascending Paralysis. He said that the patient was suffering from what was known as "Landry's disease," one of those in which the spinal cord showed no lesion. He entered the hospital complaining of numbness of his arms and legs. He quickly became worse and in a week's time lost all power of his legs and was unable to get out of bed. He had been in the habit of drinking—from four to six pints of porter daily. His cranial nerves were intact, he had no drop wrist, his temperature was subnormal, his muscle sense was normal, but his hands were cold and clammy. The thoracic movements were normal, as were those of the diaphragm and abdominal muscles. He could not sit up in bed. He had no pain in his spinal column; his sensation was normal, as were his muscular reflexes; but his muscles were flabby and he had lost the power of moving the legs. About one month after admission (Oct. 14th, 1901) the right reflex was normal and on the following day the leg could be slightly flexed. On the 26th he complained of great pain and tenderness in the calf of the left leg. On Dec 8th he had so much improved that he could walk a little by himself and last month he called to inquire if he might go on a roof to work. The treatment consisted in massage, the use of stimulating liniments, and the internal use of strychnine. Dr. Parsons quoted Gowers's views as to the site of the lesion and concluded that the paralysis was dependent on a toxic agent which had an affinity for the motor cells.

Dr. J. F. O'CARROLL exhibited two cases of Ascending Paralysis. The first was a man who entered hospital with pain over the region of the stomach He was an alcoholic; his lower eyelids were puffed, he was syphilitic, and his *urine was full of casts and amounted to about 30 ounces in* the 24 hours; his temperature ranged from normal in the morning to 101° F. in the evening of each day. After having been for three weeks in bed it was noticed that his legs were feeble. On Oct. 31st he was found to be slightly paralysed and the reflexes were lost. On Nov. 2nd he had weakness of his hands and arms but his mind was clear. At the necropsy the dura mater was found much thickened, as was the frontal bone; the brain was normal. On opening the spinal canal arachnitis ossificans was found. All these lesions were looked on as the products of the syphilis, but nothing was seen that could be considered as the cause of the paralysis. The second case was a man who gave the history of a severe wetting and a cold the result of a flooding of the lower storey of his dwelling-house. 48 hours afterwards he took to bed, where he was examined on Dec. 3rd. He lay on his back, unconscious of danger, with his limbs extended. The reflexes were absent, the urine was dribbling from his bladder, and he had had no motion from his bowels since he took to bed. He winced when the hairs of his legs were plucked out and he was unduly wakeful. On Dec. 6th he was much worse and was found to be paralysed both in his limbs and trunk. His mind was quite clear. He died on the 9th from paralysis of the diaphragm. A necropsy could not be obtained. The name "Landry's paralysis" might be looked upon as a useful clinical term for a group of well-marked symptoms but it had no pathological significance

The PRESIDENT expressed the opinion that the name "Landry's paralysis" was simply a clinical term, as was locomotor ataxy. He recognised three distinct lesions in Landry's paralysis: (1) acute multiple peripheral neuritis; (2) acute anterior cornual myelitis; and (3) acute ascending paralysis, with anterior myelitis. Dr. Graves of Dublin had placed on record the case of a sailor who was suffering from a tight and painful stricture and it was noticed that as the stricture was dilated so did his lumbar paraplegia disappear and the ratio of improvement continued *pari passu*, so that when the stricture was fully dilated the lumbar paraplegia had disappeared and the sailor was dismissed from hospital cured. M. Brown-Séquard, reasoning from the case, concluded that the peripheral irritation of the stricture had produced a reflex action in the nerve centre. Afterwards the same view was adopted by Hammond, the American neurologist, and others. The precise nature of the pathological lesion was unknown.

Dr. J. M. FINNY, Dr. W. R. DAWSON, Dr. R. TRAVERS SMITH, and others also discussed the cases.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.—The annual meeting of the supporters of this fund was held on June 4th, at the Merchant Taylors' Hall, E.C., when Princess Christian presided. The report stated that during the past year both the work done by the fund and the resources placed at its disposal exhibited a considerable increase. When the work was started 14 years ago only 39 women and girls were sent away for country holidays. Last year the number rose to more than 3000. Some of those helped could hardly be said to have had a holiday before in the whole course of their lives.

Reviews and Notices of Books.

A Text-book of Insanity. By CHARLES A. MERCIER, M.B., M.R.C.P. Lond, F.R.C.S. Eng. London: Swan Sonnenschein and Co., Limited. New York: The Macmillan Company. 1902. Pp. 222. Price 6s.

UNSOUNDNESS of mind is a very complex condition presenting much diversity of feature and symptom. Long experience in lunacy practice is necessary for acquiring a substantial knowledge of its various phases, but opportunities of this nature are only open to a few, whilst, on the other hand, some acquaintance with the subject ought to be possessed by every medical practitioner. Readers desirous of having a comprehensive view of insanity in its immediately practical aspect will find in Dr. Mercier's book exactly the kind of information which will be helpful to them, not only complete within the limits which the author has set himself, but presented in a manner *adapted for easy assimilation. Some of the writings* of eminent psychologists and alienists are, unfortunately, open to the reproach of occasional tediousness and undue elaboration. Young men making their way through the medical curriculum and practitioners immersed in the cares of their daily work cannot be expected to master large treatises on a department of medical knowledge which for most of them will be of limited application, but difficult questions as to a patient's mental condition may present themselves at any moment and the practitioner will then recognise that a certain amount of preliminary study of the subject will be of much use in assisting him to avoid the perplexities which lunacy cases so often involve. Dr. Mercier has acted judiciously in describing what he calls the forms and varieties of insanity as types, of which he gives illustrative examples, although like many who are distinctly successful as teachers he may have now and then yielded to the temptation to be somewhat dogmatic in statement and perhaps over-picturesque in some of his delineations. He set out with the purpose of writing a practically useful treatise; he has the requisite qualifications for the task, and we think that he has accomplished his intention.

A Text-book of Medicine for Students and Practitioners. By Dr. ADOLF STRÜMPELL, Professor and Director of the Medical Clinique at the University of Erlangen. Third American edition, translated by permission from the thirteenth German edition by HERMAN F. VICKERY, M.D., Instructor in Clinical Medicine, Harvard University; and PHILIP COOMBS KNAPP, M.D., Clinical Instructor in Diseases of the Nervous System. With 785 Illustrations. London: H. K. Lewis. 1901. Pp. 1242. Price 24s.

THE extent to which this text-book has been used in Germany is demonstrated by the fact that it has reached the thirteenth edition in that country. Since the second edition of this translation was published in 1893 seven new editions have appeared in Germany, so that the book has been almost wholly rewritten. It still retains all the merits of the earlier production, but now it has all the advantages of being fully in line with the most recent medical investigations. The translators have performed their task well but have kept as closely to the original as seemed to be consistent with clearness. They have also added a chapter upon Plague and various notes which should prove of assistance to the practitioner. These additions are inclosed in brackets and are signed with the initials of the translators so as to distinguish them from the unsigned additions to the text (also in brackets) which have been contributed by Dr. Frederick C. Shattuck, Jackson Professor of Clinical Medicine in the Harvard University. The doses in the metric system have been changed to the equivalents in apothecaries' weight, the original doses being retained in parentheses. This was necessary in order to render the work of true practical use to the English practitioner.

The general scope of a work of which there have been so many editions requires little explanation. The author has brought the facts of clinical experience into the closest possible relation with the data of pathological anatomy and of general pathology. He has also, in discussing therapeutics, attempted to deduce from the nature of the symptoms a basis for rational medical opinion and treatment, although he has been careful not to undervalue the importance of practical experience. Needless to say, that Professor Strümpell being such a careful and indefatigable observer the present edition has been brought fully up to date, and especially is this to be noticed in therapeutics, the most recent forms of treatment, by drugs or otherwise, being duly described and commented on.

The work is a large one and will be found especially useful for reference by practitioners who wish to have a trustworthy source of information which can be readily consulted in case of need.

Manual of Antenatal Pathology and Hygiene: the Fœtus. By J. W. BALLANTYNE, M.D., F.R.C.P., F.R.S. Edin., Lecturer on Midwifery and Gynæcology, Medical College for Women, Edinburgh; Lecturer on Antenatal Pathology and Teratology in the University of Edinburgh (1900); Examiner in Midwifery in the University of Edinburgh; Assistant Physician, Royal Maternity Hospital, Edinburgh; Honorary Fellow of the Glasgow Obstetrical and Gynæcological Society and of the American Association of Obstetricians and Gynecologists. With 14 coloured plates and 55 illustrations in the text. Edinburgh: William Green and Sons. 1902. Pp. 527. Price 20*s.* net.

THE high position that Dr. Ballantyne holds amongst teratologists is well known and it is a matter for congratulation that we should have in this country one who has accomplished so much valuable work upon the subject. He has made a very large number of original contributions to fœtal pathology and has done more than any other writer to place our knowledge upon a sure and scientific basis. A perusal of his latest work upon antenatal pathology and hygiene enables us to realise not only what is already known but also how much more remains to be learnt before our knowledge of this branch of medicine can be said to be in any way perfect. This work of Dr. Ballantyne cannot fail to arouse a great deal of interest in the matter amongst students of obstetrics and pædiatrics and should lead many men to attempt to make original observations for themselves in a field of work which so far has been little tilled. The difficulties of the study are undoubtedly great and we fear but little real progress will be made, at any rate in antenatal pathology, until the prematernity hospital, for which the author so eloquently pleads, has been established. The present volume, which deals mainly with fœtal physiology and pathology, is to be followed by a second volume in which teratology and morbid heredity will be considered. It is scarcely possible within the scope of a review to do adequate justice to the amount of original work and investigation that Dr. Ballantyne has summarised within this book. As he says, he has had the good fortune to have been able to examine no less than 300 specimens of antenatal morbid states and he can, therefore, speak with all the weight of so large an experience. Further than this, his knowledge of the literature is of the widest character and the result is a book full of the most interesting facts enlivened by some most suggestive and ingenious theories.

The sections that will appeal chiefly to the practitioner are those upon the Anatomy and Physiology of the Fœtus. The fascinating question of the protective rôle played by the placenta and the transmission of various morbid conditions and specific diseases through its agency from mother to child are very fully considered and discussed. How small our knowledge of these important relations is the author's conclusions show. He writes: "There is experimental proof that some poisons reach the fœtus and sometimes produce structural alteration in the fœtus and placenta." The chapter upon Antenatal Diagnosis is one that we commend to all those who have opportunities of watching pregnant women during the course of their pregnancies. It contains many most interesting suggestions. When we consider the important social and moral questions that are concerned in what the author terms "germinal therapeutics" we cannot but recognise the necessity for a more profound knowledge of the problems of antenatal pathology, bound up as they are with the difficult question of morbid heredity and destined as they are to play a very large part in the future moral and physical welfare of the race.

The book is one of the most interesting and instructive that it has been our good fortune to read and one that we cannot too strongly recommend to all those who, like the author, recognise that in this subject—

"Little we know;
Much is to be known;
Hardly is it to be learned."

The Accessory Sinuses of the Nose: their Surgical Anatomy and the Diagnosis and Treatment of their Inflammatory Affections. By A. LOGAN TURNER, M.D., F.R.C.S. Edin., Surgeon for Diseases of the Ear and Throat, Deaconess Hospital, Edinburgh. With 40 plates and 81 figures. Edinburgh: William Green and Sons. 1901. Pp. 211. Price 12*s.*

DR. LOGAN TURNER has presented us with a book of more than usual interest and one that is full of valuable information based on careful scientific research. The illustrations are excellent examples of anatomical drawings and are exceptionally clear, being far superior to those which are usually found in medical literature. Dr. Turner not only adds most materially to our anatomical knowledge but he has given clear and valid reasons for any exception which he takes to the views of other investigators. He has embodied in this book the results of careful and laborious work carried out in relation to the measurements of the accessory cavities of the nose and on the effects of transillumination for the purposes of anatomical research and of clinical diagnosis of pathological conditions; the work had for its foundations a lecture delivered by Dr. Turner at the Royal College of Surgeons of Edinburgh on Illumination of the Air Sinuses of the Skull with Some Observations upon the Surgical Anatomy of the Frontal Sinus and his prize essay on the Racial Characteristics of the Frontal Sinuses. The skulls collected by the author's father, Sir William Turner, which are now in the Edinburgh Museum, placed no less a number of crania than 578 at Dr. Turner's disposal and included amongst them examples of most known races.

Amongst the chief features and points of interest in the book are the plates and observations which deal with the depth to which the horizontal portion of the frontal sinus may pass in a backward direction above the upper orbital wall, between the orbit and anterior cranial fossa; in one skull examined it passed back to the optic foramen. Also the height may be much greater than usual, in one case being as much as two and a half inches. In considering the depth of the sinus at various parts Dr. Turner points out that there is not any material difference between that behind the ophryon and glabella, which does not support the claim put forward by Dr. Rolleston that antero-posterior measurements of the skull, if taken from the ophryon, give a more correct brain index than if taken from the glabella. To determine the extent to which the frontal sinus extends behind the ascending portion of the frontal bone transillumination was adopted and in numerous instances the sinuses marked out by the aid of the lamp were opened and the absolute trustworthiness of the method was proved. Dr. Turner, however, remarks that valuable though this method is in the dry skull, yet as an aid to diagnosis in suppuration in the frontal sinus it is of small practical value. Another point of considerable importance demonstrated by the author is the great depth and extent to which an anterior ethmoidal cell may penetrate (*vide* Fig. 1, Plate XVIII.), and the importance of a knowledge of such instances in relation to pressure effects on the optic nerve is clearly brought out. The situation and importance of the bulla ethmoidalis receive due attention and are the better appreciated on account of the very valuable plates in which the bulla is depicted.

There is much less that is new in the description of the maxillary sinus, chiefly on account of the fact that far more has been written on its anatomy and pathology than is the case in that of the sphenoidal sinus, but the plates and description as to its development are interesting and instructive. Dr. Turner points out a fact which has not, we believe, been previously noted—namely, that when the frontal sinus and the maxillary sinus open into a common duct it is possible to infect the frontal sinus whilst washing out the antrum if much force is employed. He combats the term "frontal cell" as employed by Hartmann to designate the anterior ethmoidal cells and the term "fronto-ethmoidal" as employed by other writers, showing that both terms are anatomically incorrect, and, as he truly remarks, by adhering to correct anatomical nomenclature there is less likelihood of confusing students. The results of the investigations on the extent of the frontal sinus in the various races of mankind and also the brief record of the presence of frontal sinuses in animals are most interesting and confirm the views of previous writers, though the author has here added new material by considering the height that the sinuses attain in relation to the height, length, and breadth indices. The concluding chapters on the pathology and treatment of the various diseases of the respective sinuses are not very full and do not reach the high standard of the rest of the book.

The whole work is admirably produced; the text is good, the subject-matter is lucid and tersely put, and the anatomical parts are full of interest and suggestion. The book will be of great value and assistance to all who wish to make themselves better acquainted with the normal and abnormal varieties of the accessory sinuses of the nose.

LIBRARY TABLE

Living Rulers of Mankind. By the Rev. H. N HUTCHINSON, F.R.G S. London · George Allen. 1902. Demy 4to, pp. 206. Price 7*s.* 6*d.*—This interesting book by Mr. Hutchinson, the editor of "The Living Races of Mankind" and the author of "Marriage Customs in Many Lands," appears opportunely just before the coronation of King Edward VII., when the representatives of most of the nations of the earth will be assembled among us. In Vol. I. are considered the rulers, among others, of Austria-Hungary, Belgium, China, Denmark, Egypt, France, Germany, Italy, and Great Britain and her dependencies. The articles are illustrated profusely with portraits of the different rulers, their wives and children, their palaces and pleasure resorts. The character sketches of the different monarchs, presidents, and viceroys, though written in courtier-like language—indeed, the purpose of the book is rather to show that kings, queens, and presidents are very much to the front in the present day—are accurate and enable the reader to get a grasp of each ruler's personality. The illustrations, of which there are no less than 245 for the embellishment of some 200 pages, are beautiful examples of process reproduction. The portraits of our King and Queen and of the Queen of Roumania (Carmen Sylva) are given in colours, a really beautiful picture of the poet-queen of Roumania appearing as a frontispiece.

A Surgical Handbook for the Use of Students, Practitioners, House Surgeons, and Dressers. By FRANCIS M. CAIRD, M.B., F.R.C.S. Edin., assistant surgeon to the Royal Infirmary, Edinburgh; and CHARLES W. CATHCART, M.B. Edin., F.R.C.S. Eng. and Edin, surgeon to the Royal Infirmary, Edinburgh. With very numerous Illustrations. London: Charles Griffin and Co., Limited. Eleventh edition. 1902. Pp. 323 Price 8*s.* 6*d.*—This useful little work has now been before the professional public for 13 years and the fact that a new edition has appeared nearly every year of that time is in itself an evident proof of the appreciation with which it has been received. Every edition has been an improvement on its predecessor and the present issue is certainly excellent. In their daily work there are many difficulties encountered by the house surgeon and by the practitioner, for the overcoming of which the ordinary text-books of surgery seldom afford any assistance, yet here will be found exactly what is needed. There are chapters on special subjects falling within the domain of surgery about which, however, many are ignorant; we may mention massage and the surgical applications of electricity. An appendix contains accounts of several subjects which do not come within any of the chapters of the work, such as the ambulant treatment of fractures, the sterilising of dressings, and sick-room cookery receipts. It is unnecessary to praise the book to those who know it; and to any student who does not know it we can only say that he will certainly benefit by the practical directions and hints which it contains.

The Ready Reference Handbook of Diseases of the Skin. By GEORGE THOMAS JACKSON, M.D. Col., Chief of Clinic and Instructor in Dermatology, College of Physicians and Surgeons, New York, &c. With 80 Illustrations and 3 Plates. Fourth edition, thoroughly revised. London: Henry Kimpton. 1902. Pp. 642. Price 12*s.* 6*d.*—This is a treatise on dermatology in which the several articles are arranged in alphabetical order. This arrangement has in a small treatise the advantage that the reader can refer with ease to any particular disease. In a larger work the inconvenience of the separation of cognate subjects would more than counterbalance this We were able to express a very favourable opinion of the previous edition and we may say that this issue has a number of new sections and the whole has been thoroughly revised, as a reference to the third edition readily shows. Fortunately, the additions are compensated for by diminution elsewhere, so that the book has not increased in size. The work can be confidently recommended to all those who desire a general knowledge of dermatology, for it is written by a physician who is well acquainted with his subject and who has evidently had much experience in teaching it.

A Clinical Manual of Skin Diseases, with Special References to Diagnosis and Treatment for the use of Students and General Practitioners By W. A. HARDAWAY, A.M , M.D., Professor of Diseases of the Skin and Syphilis in the Missouri Medical College, St. Louis; ex-President of the American Dermatological Association. Second edition, revised and enlarged, with 42 Engravings and two Plates. London: Henry Kimpton. 1901. Pp 557. Price 10*s* 6*d.*—In the first edition of this work the various diseases of the skin were arranged alphabetically but the author has thought well in this issue to present the diseases under a regular system of classification. There is much to be said for each method but the present plan is more scientific, though, as our present systems of classification of diseases of the skin are little more than provisional, the arrangement will probably need revision in subsequent editions. The work, though enlarged, does not contain more than the average student may reasonably be expected to know", and this is important, for there is probably no class of diseases more neglected at the present time than those affecting the skin. There is one statement in the work to which we may draw attention. We are told, in the account of the treatment of scabies, that "it is a *sine quâ non* that the underclothing and sheets be disinfected by boiling If this were so most out-patient cases would never be treated with success, for however carefully instructions may be given to them to boil or to bake their clothes they are very rarely indeed carried out. Moreover, it has been shown that recurrence does not occur in more than 5 per cent. of the cases when the clothes are not disinfected in the least.

The Cerebro-Spinal Fluid Its Spontaneous Escape from the Nose, with Observations on its Composition and Function on the Human Subject By STCLAIR THOMSON, M.D, M R.C.P Lond, F R.C S Eng, physician to the Throat Hospital, Golden-square, surgeon to the Royal Ear Hospital, London. London Cassell and Co, Limited. Pp. 140. Price 5s —This book owes its existence to the fact that Dr Thomson a few years ago discovered that a young woman in apparently good health was suffering from the escape of cerebro-spinal fluid from one nostril. No cause could be found and but little inconvenience was occasioned. This case led the author to examine medical literature for the records of other similar cases and he succeeded in collecting about 20 instances of this curious anomaly In many of the cases the liquid was not diagnosed as cerebro-spinal fluid, but the author adduces reasons for his opinion that this was its true nature. In many instances this hydrorrhœa was associated with cerebral symptoms and with optic neuritis, and we acknowledge that Dr Thomson has proved his point for at least many of the cases In the case under his care the analysis by Professor Halliburton was amply sufficient to identify the liquid as cerebro spinal fluid. The cases collected consist of nine in which the identity of the liquid with cerebro-spinal fluid was indubitable, 12 in which the discharge was very probably cerebro-spinal fluid, and eight other cases which were possibly of this nature The pathology of the affection is discussed, but the author does not arrive at any definite conclusion. As to the treatment, nothing is known that can check the flow An appendix contains observations on the composition and function of human cerebro-spinal fluid which have already appeared in the Proceedings of the Royal Society The volume is an interesting monograph on a rare but important morbid condition and deserves study by all who have to deal with a case of watery discharge from the nose

THE FESTIVAL DINNER OF THE POLYCLINIC

(MEDICAL GRADUATES' COLLEGE.)

THE members of the Polyclinic held their festival dinner on June 5th at the Criterion, Piccadilly-circus, London, under the chairmanship of Mr H. H. ASQUITH, K.C., M P Amongst the guests seated on the right hand of the chairman were Lord Davey, the Archdeacon of London, Sir J Crichton Browne, Mr A. Lee, M P, Mr B L. Cohen, M.P, Sir John A Cockburn Mr J Hall, K.C., Sir Owen Roberts, Mr D Coghill, M.P, Sir Joseph Fayrer, Professor Clifford Allbutt, Dr R. Farquharson, M P, and Inspector General Turnbull. To the left of the chairman were Sir William H. Broadbent, Sir Alfred C. Lyall Sir A. Geikie, Mr J Hutchinson, Sir F Abel, Dr J G Ponce, Sir John W Tyler, Mr T P O Connor M P, the Hon E. R. Belilios and Sir W Pearson, M P

After the usual loyal toasts had been honoured the toast of "The London Polyclinic" was proposed by Mr ASQUITH who said that the objects of the Polyclinic were twofold It was a charitable institution in the best sense of the word—that was to say, without coming in the least degree into competition with the hospitals it provided a means by which persons who could not themselves afford to pay the usual fees for consultation could be brought by their medical man to the Polyclinic and there get in consultation with that medical man the best medical advice that the most skilful members of the profession in London could provide. During 1901 very nearly 1200 patients had received this gratuitous consultation advice. The Polyclinic had another object which was still more important. There was no profession in the world in which it was more urgent that facilities should be provided for after education than medicine because it was every year receiving vast accumulations of new observations which must profoundly modify the theory and treatment of disease. To maintain themselves abreast with the scientific pursuit of medicine in other countries they must have the means and the opportunities of readjusting their conceptions according to the altered experience which new facts were constantly bringing into view He pointed out what had happened by means of research in regard to tuberculosis and malaria and he hoped that a similar fruitful voyage of discovery might be made concerning the disease of cancer Those results were only to be obtained by research and coöperation and the Polyclinic would afford when properly equipped, an admirable theatre for post-graduate research and attain something like a conservative and combined body of scientific results The Polyclinic, therefore, was entitled to the support of the medical profession and of the outside public. Mr Asquith concluded by hoping that their festival dinner would engender fresh interest in the Polyclinic which he believed was no less advantageous and important to medical men than it was likely to be useful and beneficent to the public in this country

Sir WILLIAM BROADBENT, in replying to the toast said that it was now felt on the part of the medical profession as a whole that they must be alive to the great scientific questions which came before their notice in their ordinary day s work The Polyclinic provided for three demands from the medical profession. It supplied instruction in certain special departments, such, for instance as diseases of the eye, it supplied the want felt by medical men seeking further clinical experience, and lastly, it was the object of the Polyclinic to afford opportunities for study in chemistry, biology, and bacteriology What the Polyclinic ought to have for work of that kind was a hospital equipped on the scale of the Johns Hopkins Hospital, to take patients from every class of society on the recommendation only of the medical attendant.—This toast was also replied to by Dr THEODORE WILLIAMS.

The toast of "The Empire" was proposed by Mr JONATHAN HUTCHINSON who said that the Polyclinic desired to bring its work to bear upon the community of this great empire. The Polyclinic was not in a flourishing state but it was desired to extend its influence to the very ends of the earth. It was not an insular institution but gained all it could from all parts of the world. The public was therefore asked to help liberally in the work. This toast was responded to by Mr ARTHUR LEE, M.P, and by Sir JOHN COCKBURN.

Dr THEODORE WILLIAMS announced that donations had been received amounting to over £500.

Sir JAMES CRICHTON BROWNE then proposed the health of the Chairman, to which due acknowledgment was made and the company separated after singing the National Anthem.

A HOME for medical men and persons "belonging to the medical profession" who have become reduced in circumstances is to be established in Moscow Geheimrath Rasswetow whose death occurred not long ago, has bequeathed to the city a sum of 800 000 roubles (£84 600) for the erection and maintenance of the home

GLASGOW SOUTHERN MEDICAL SOCIETY —A meeting of this society was held on May 29th Dr. J Stewart the President being in the chair —Dr Archibald Young gave an interesting address on his experiences as a civil surgeon with the troops in South Africa. He submitted a detailed account of numerous surgical cases that came under his treatment The lecture was illustrated by a large number of interesting lantern slides

THE LANCET.

LONDON: SATURDAY, JUNE 14, 1902.

The Recent Session of the General Medical Council.

THE proceedings at the seventy-fourth session of the General Medical Council came to an end on Tuesday, June 3rd. It had been hoped, as a special session of the Council had already been held this year, that the proceedings would have been brief and would not have compelled the members of the Council to remain in harness after the last day of May. This hope received considerable support from the facts that the penal cases before the Council were not numerous and were heard with commendable alacrity. The most important of these, the case of Dr. ROBERT RENDALL, whose connexion with the Liverpool Victoria Legal Friendly Society at Great Yarmouth came under the unfavourable notice of the Council last November, is considered at some length in another column. It is gratifying to find that no other case came before the Council of any practitioner associating himself with medical societies which systematically canvass for patients, a fact which suggests somewhat forcibly that the medical profession is beginning to take a common line in the important matter of contract practice. Also, no case of covering came before the Council, a satisfactory incident which proves that the evils rampant under the old system of unqualified assistants have practically disappeared. That this is so was known to us. The columns of THE LANCET have for many months been to all intents free from correspondence upon this subject, while reference to our back files shows that until recently there was no topic upon which we were more frequently addressed. Weekly, almost daily, we were wont to be consulted as to the scope of the work of the unqualified assistant and the license that should be permitted to the dispenser. But this has now ceased and the profession as a whole has decided to acquiesce in the wise policy of the General Medical Council with regard to the employment of persons who have not received a complete medical education. That this is so redounds to the credit of the profession, for undoubtedly many practitioners have been put to considerable expense and inconvenience that they would have been spared under the old *régime*, but spared at the expense of the public safety.

The most interesting debate of the session was undoubtedly that which arose out of a request from the Council of the British Medical Association that the General Medical Council would receive a deputation to consider the subject of the preliminary education of the medical profession. The request, which was justified by a somewhat drastic report from the Preliminary Education Committee of the British Medical Association, was referred to the Executive Committee of the General Medical Council and was refused by that committee. The Executive Committee made no secret of their view that they considered that the good work of the General Medical Council in striving to advance the standard of preliminary education in the medical profession had been completely ignored by the British Medical Association. A breezy discussion led, however, to a better understanding and on the first day of the session it was decided that the Education Committee of the General Medical Council, on behalf of that Council, should receive a deputation from the Council of the British Medical Association. The deputation attended at the offices of the Council on Saturday, May 31st. Dr. G. B. FERGUSON, the President of the British Medical Association, repudiated the idea that the Preliminary Education Committee of the Association was antagonistic in any way to the work of the General Medical Council and pointed out that the desire of the Association was to strengthen the hand of the Council by registering the interest of the Association in a most important professional question. Dr. MAURY DEAS and Dr. W. GORDON, both of Exeter and representing the South-Western Branch of the British Medical Association, then spoke with considerable detail in support of the proposition that with the existing requirements of the General Medical Council there is no adequate guarantee that a medical practitioner has received a liberal education befitting a member of a learned profession. Sir JOHN BATTY TUKE, on behalf of the Education Committee of the General Medical Council, promised that a reasoned answer should be given to the various points raised in the speeches of Dr. DEAS, Dr. GORDON, and other gentlemen forming the deputation, and at this answer the profession will look very carefully. There can be no doubt that the General Council of Medical Education and Registration—to give the body its full title—has for many years tackled the side of its duties bearing upon education with zeal and vigour; but the executive of the British Medical Association, being more in touch with the mass of the medical profession in this country, may be able to offer to the Council suggestions of a nature which it will be of great value to the Council to discuss. We are glad, therefore, that the Council received the deputation. It is well that the Council should keep in touch with the British Medical Association and should use the opportunities which that Association enjoys of learning the views of the profession at large upon a matter of such prime importance as preliminary medical education.

But perhaps the most important circumstance of an unsensational session has been the complete revelation to the world of the pecuniary position of the General Medical Council. That the finances of the Council have been in an unsatisfactory state has been patent for some time to those who have been sufficiently interested to inquire into the matter—a definition which hardly includes the whole *personnel* of the Council—but the report of the Finance Committee of the Council for the year 1901, no less than the report of the Special Financial Relations Committee appointed last year, have now made clear to all what a difficult position has been reached. The Finance Committee reported that the income of the General and Branch Councils for the year ending Dec. 31st, 1901, was £8557, and that the expenditure for the same period was £10,065, showing a deficit of £1508. The Financial Relations Committee reported that the deficit on the Council's income and expenditure account on the average of the last seven years has amounted to full £1200 per annum—a position which certainly justified Mr. HORSLEY moving in the Council, by way of raising a general debate, "that the principles of amendment of the financial position of the Council embodied in the report of the Financial Relations Committee be approved." The various obvious steps for increasing the income of the Council, such as the increase of the fee for registration as a qualified practitioner, the institution of a fee for registration as a medical student, and the payment of an annual licensing fee, then came under discussion. The first method, rightly as we think, appeared to commend itself to the Council, while the third was rejected in a pronounced manner The Financial Relations Committee being reappointed, the whole subject will come before the Council again next session and will, we trust, be taken early in the proceedings, for it is one of urgent importance. In the meantime payments to the sinking fund have been discontinued by the Council, largely owing to an admirable statement by Mr TOMES which in a convincing manner showed that in the circumstances of the Council this fund was a foolish one and based on fallacious finance. "Is it," asks Mr. TOMES's addition to the report of the Finance Committee, "the business of the Council of to-day, with financial difficulties in full sight and with an income inadequate and likely to be still more inadequate, to be making provision not out of its surplus but as an addition to its deficits for the Council of 50 years hence?" The answer to this question can only be "No," and all the more emphatically "No" that the chief asset of the Council—namely, its freehold property—is one that must appreciate, so that the Council, in spite of itself, will be richer in 50 years than it is now. None the less the abolition of the sinking fund is an abandonment of all pretence to economy—false economy though it may have been. Therefore it behoves the Council to put its financial affairs rapidly into order and if the assistance of the Government to any necessary Parliamentary measure is required it should be promptly forthcoming It *should* be, we say, but recent experience makes us doubt whether it *would* be.

◆

The Lessons of Dr. Rendall's Case.

AT the meeting of the General Medical Council on May 29th a highly satisfactory conclusion was arrived at in the case of Dr ROBERT RENDALL of Great Yarmouth. While rejoicing at the excellent vindication of professional feeling which this case affords we may also congratulate Dr RENDALL upon his good sense in not pushing further his opposition to the pronounced opinion of the General Medical Council To whatever lengths and at whatever expense he had pressed his cause the verdict not only of all his professional brethren, but also we feel confident of the courts of law, would have been unequivocally against him. He has wisely availed himself of the interval afforded him at the penultimate meeting of the Council to reconsider his position and has resigned his post as medical officer to the National Medical Aid Company, Limited, and as medical referee to the Liverpool Victoria Legal Friendly Society. These bodies will, it is pretty clear, have considerable difficulty in providing themselves with a substitute in the position vacated by Dr. RENDALL Nor will such a man, should he be forthcoming, be allowed to occupy undisturbed the post from which his predecessor has been forced by the organised opinion of the profession in Yarmouth, the prosecution of the Medical Defence Union, and the consequent action of the General Medical Council. The behaviour of the medical men of Great Yarmouth, united under the name of the "Great Yarmouth District Committee," and represented by the President, Mr. A. H. MOXON, and the secretary, Mr W. E. WYLLYS, has been from the outset an example of proper professional conduct. There has been shown no animus, no malice, against one who was acting contrary to the well-declared feelings of his fellows, and at the same time a firm determination has been plainly evinced that respect would be exacted for the rights and dignity of the profession. In a word, the profession in Yarmouth resolutely refused to allow specious companies to thrive by "sweating" medical men If medical men in all districts would but see as clearly as their Yarmouth fellows have done the issues that are really raised in such cases as this and would combine in the same way against them many of the hardships which are complained of in private practice would soon melt away. That the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company, Limited, actively canvassed for patients may be regarded, in the light of events, merely as a fortunate accessory which brought their medical officer securely under the ban of the General Medical Council which had passed a resolution "strongly disapproving practitioners associating themselves with medical aid associations systematically canvassing and advertising for the purpose of procuring patients." That associations which practise in this way are to be shunned as an unclean thing must be obvious to even the youngest practitioner of medicine.

We wish it were equally clear to all medical men that other evils less obvious but no less derogatory are inherent in the majority of contract practice as it exists at present. Much of the contract practice of this country lowers the status of the medical man and provides to the public a benefit much more apparent than real. Why, then, does it exist? The answer is simple. The system is maintained by middlemen for their own pecuniary advantage which is gained at the expense of the medical officers. The "middleman" may be a company or a secretary, or some kind of "friendly" society. The "friendliness" is introspective and limited. The society may be a good "friend" to a few, it is apt to be an over-rated friend to the sick poor, and no friend at all to those who are so unhappy as to serve it medically. In so far as friendly societies are instruments for encouraging thrift and provision among the poorer classes they have our hearty support; their medical benefits should be only a side issue—a part of a large scheme for the national betterment of the working classes. On examination it will be found, however, that they mostly live and flourish by their medical aid society and by nothing else. Take away the medical aid, which is provided, as a rule, by underpaying a medical man, and we find that the other provisions of the friendly society are worth little. To have a medical practitioner who can be summoned at any moment and who, if he does not come, can be righteously abused for "not doing what he is paid for"; to be able to exact from him for a few shillings attentions which from year to year would only be adequately paid for by many pounds—is a bait which lures as subscribers to many so-called friendly societies persons whose wages and private means would warrant their employing a medical man's individual attention. The medical man is on the hook and the "friendly" society's promoters wield the rod. The general public naturally has its mouth open to swallow with small scruple the bait dangled before its eyes. That the public really benefits is very unlikely. It buys a right to medical attention at a ridiculously low price. What is the value likely to be of the labour of a man who knows that he is undertaking twenty times the amount of work that he can possibly perform carefully or even competently. And that many medical men are asked to contract for the carrying out of impossible tasks is well known to our readers. What is likely to be the attitude of mind of the medical man when summoned repeatedly to a patient who is paying a few pence while he could afford to pay, and ought to be paying, as many pounds? Does he go prepared to employ all the care and skill that he is capable of, or does he go imbued with the notion of getting through the case as quickly as possible and so of being "done" by it as little as may be? We believe that in the vast majority of cases he goes uncomplainingly to do his best. But even medical practitioners are human. We have compared their positions to that of a bait. Well, even the worm on a hook will turn.

Contract practice there must be, but there is no reason why contract practice should not be fair to both of the contracting parties. At present it is generally fair to neither. It is unfair to the medical man who is required to give much service at the price of very little; it is unfair to the subscriber who cannot by the circumstances of the case get from the medical man anything like the attention which he believes himself to be paying for. Let medical men stand by one another in insisting upon decent terms and upon making those terms themselves directly with those who are to be their patients and contract practice may benefit both parties. The public has no need to fear the generosity of the profession; medical men have never been conspicuous for an exacting nature; they give the pound of flesh much more often than they take it. We wish our readers to realise that by entering upon contract practice with many medical aid societies they often do not benefit those to whom their services are offered and they in many instances place themselves at the same time in a position which is unfair and undignified and which should never be demanded of them.
